Argo Float Array

Positions of 3000 mid-depth floats are shown 3 years after deployment at 3° latitude and longitude spacing in the NRL global eddy-resolving model (courtesy H. Hurlburt). The mid-depth flow shows no tendency to produce clumps or gaps.

6 -12 hours at surface
to transmit data to satellite

Total cycle time 10 days

Descent to depth
~10 cm/s (~6 hours)

Salinity & Temperature
profile recorded during ascent
~10 cm/s (~6 hours)

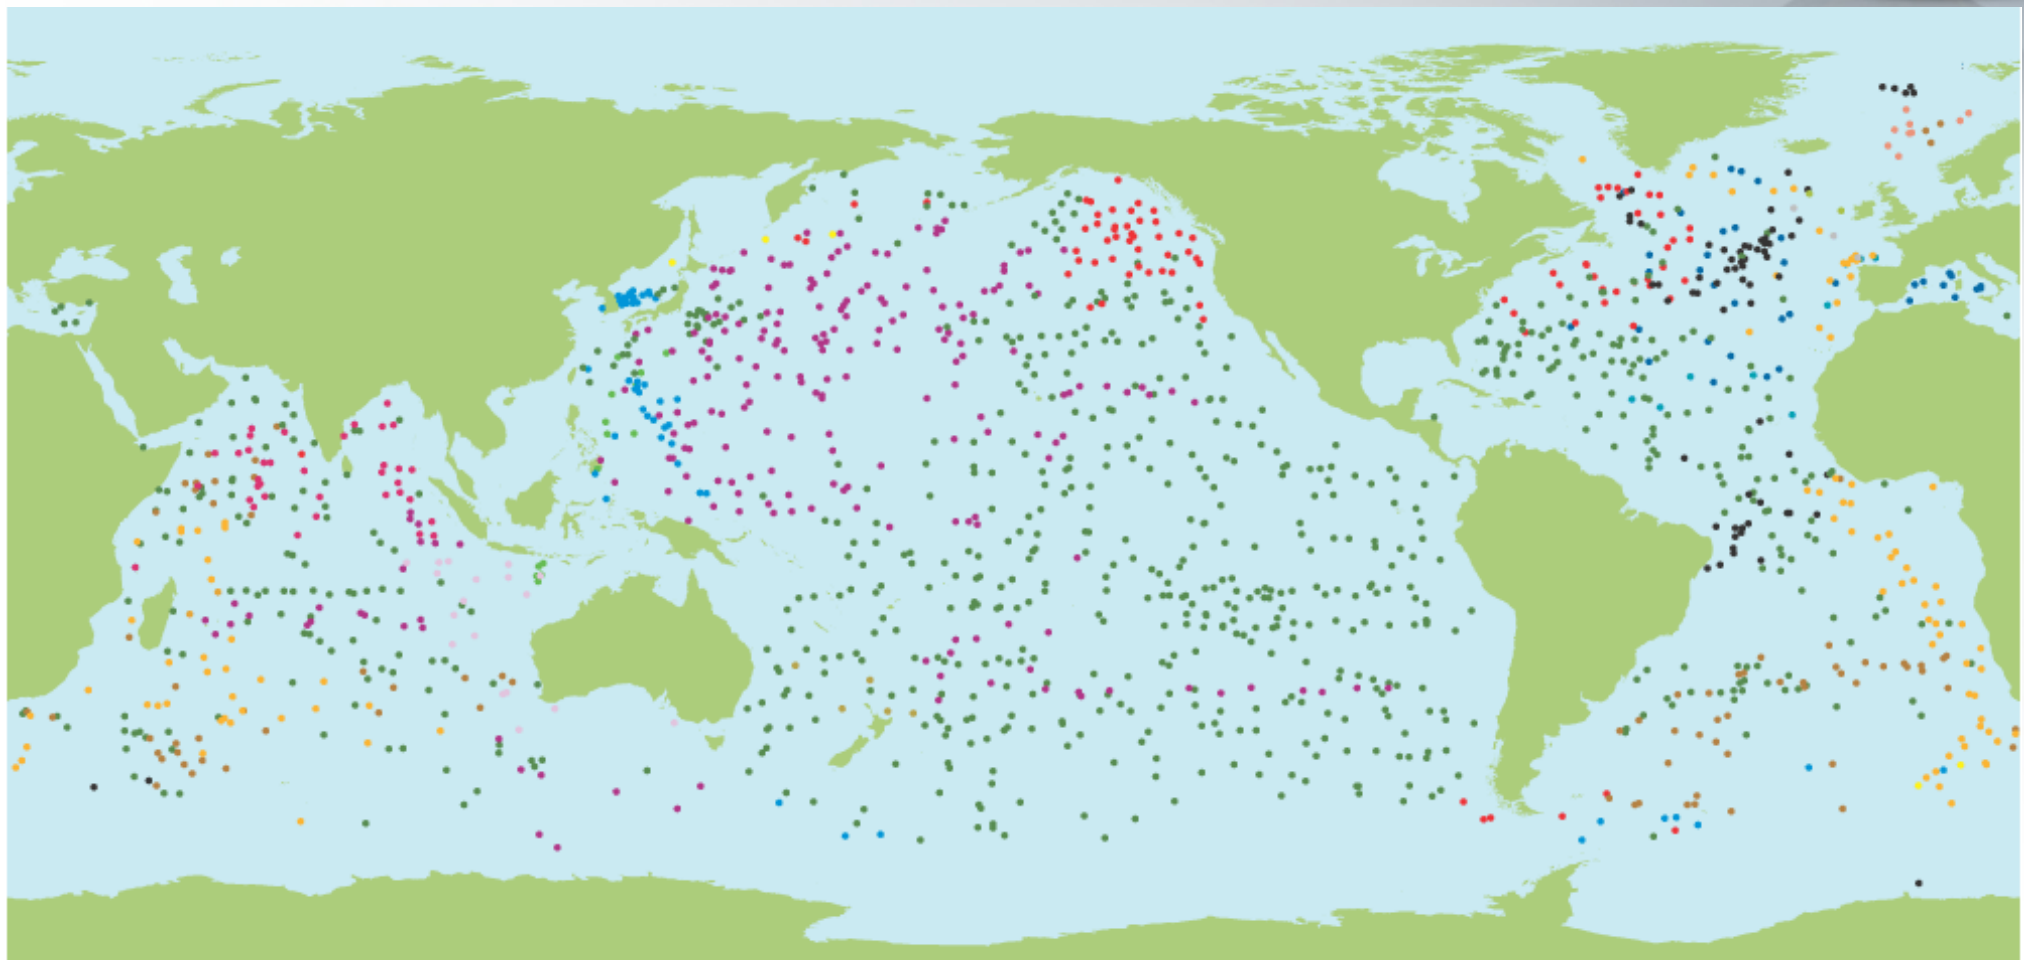

1000 db (1000m)
Drift approx. 9 days

Float descends to begin
profile from greater depth
2000 db (2000m)

Argo Real-Time Status

(Last Update: 06-MAI-2005 04:52 UTC) - **1804** Active Floats

Argo float deploying countries 2004:

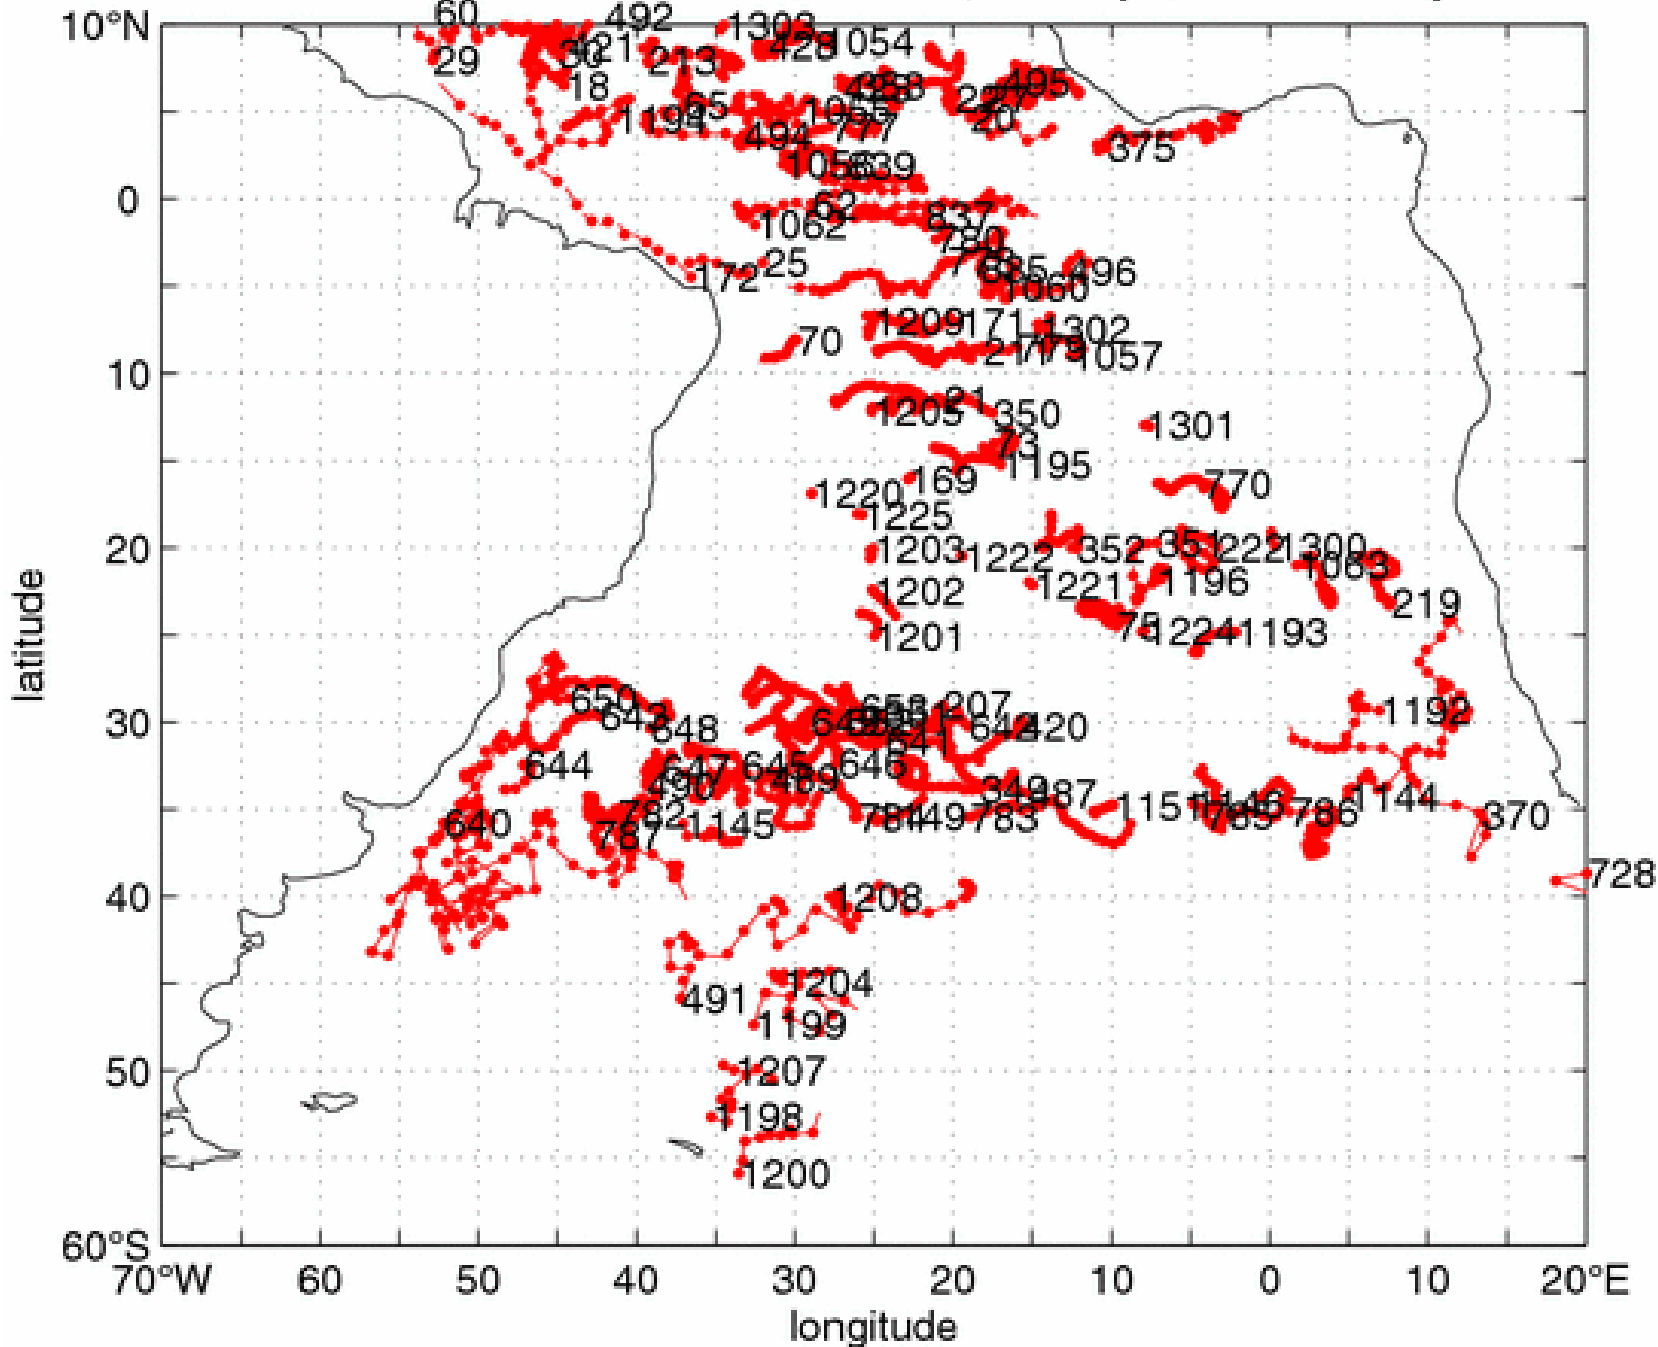

US Argo Profile Locations Observed in the Last 12 Days

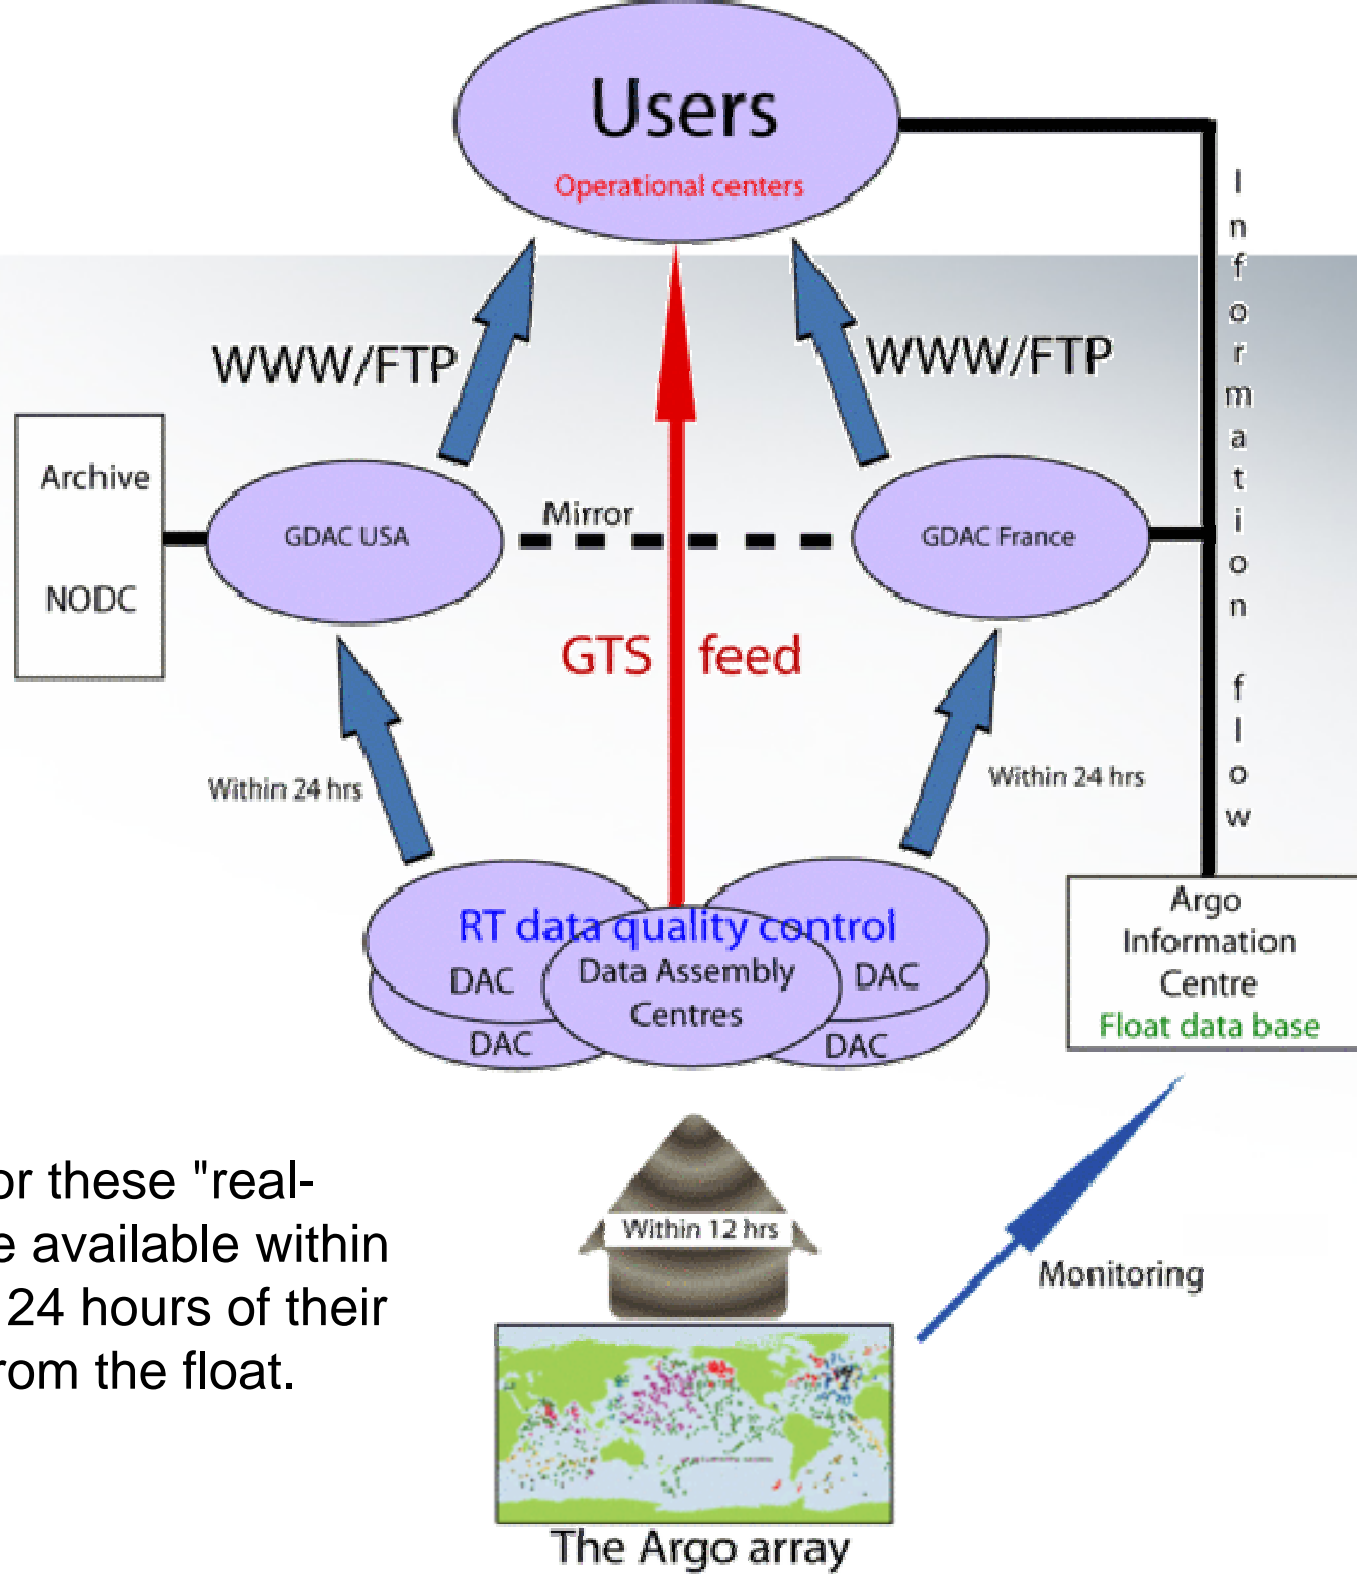

Atlantic Ocean

May 1, 2005

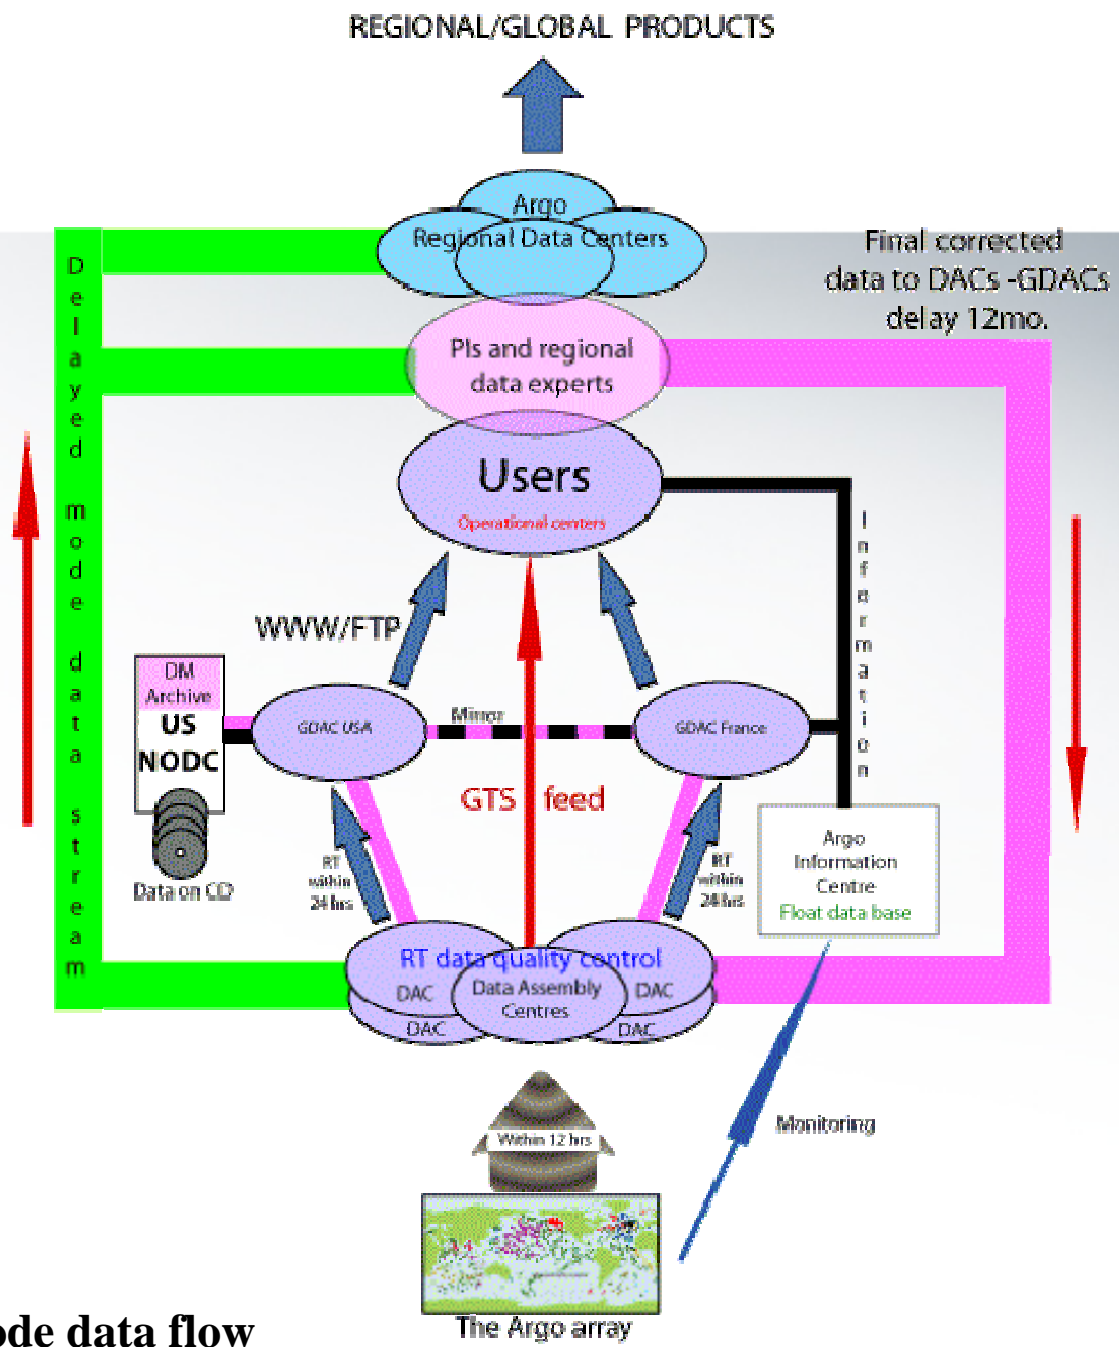

USA ARGO Floats – South Atlantic Ocean, 01-May-2004 – 01-May-2005

The target is for these "real-time" data to be available within approximately 24 hours of their transmission from the float.

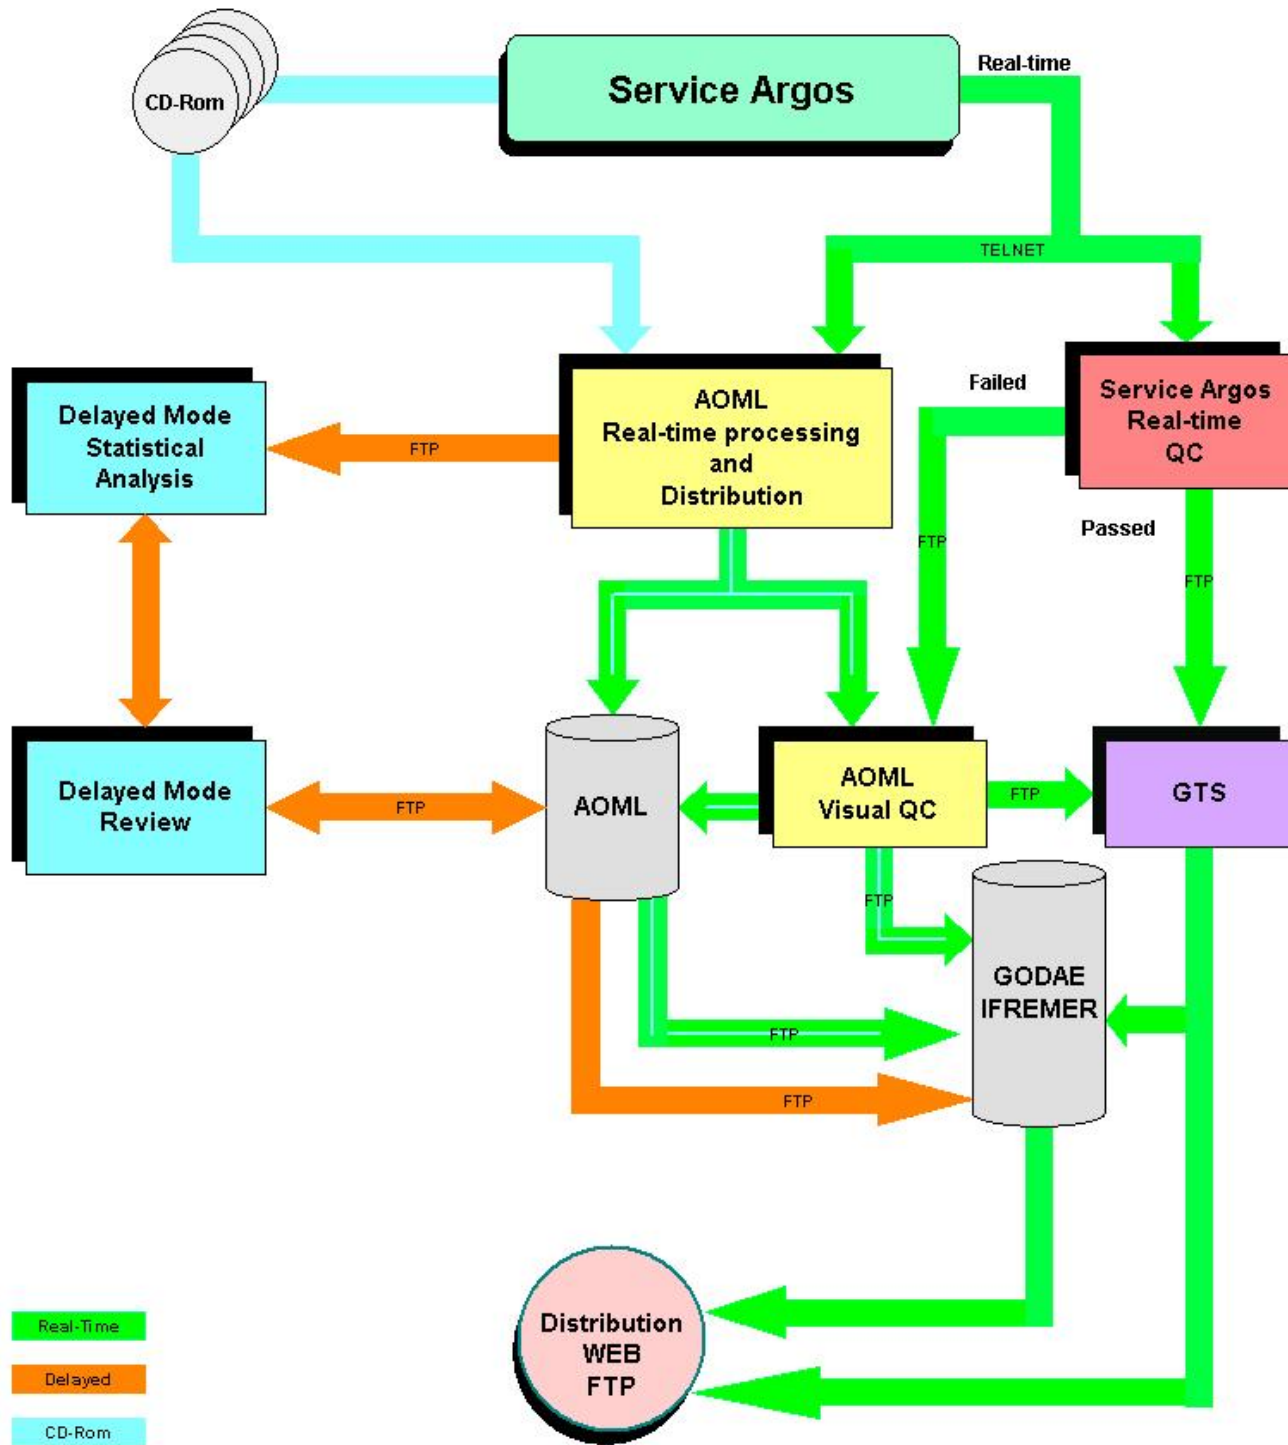

Real time and delayed mode data flow

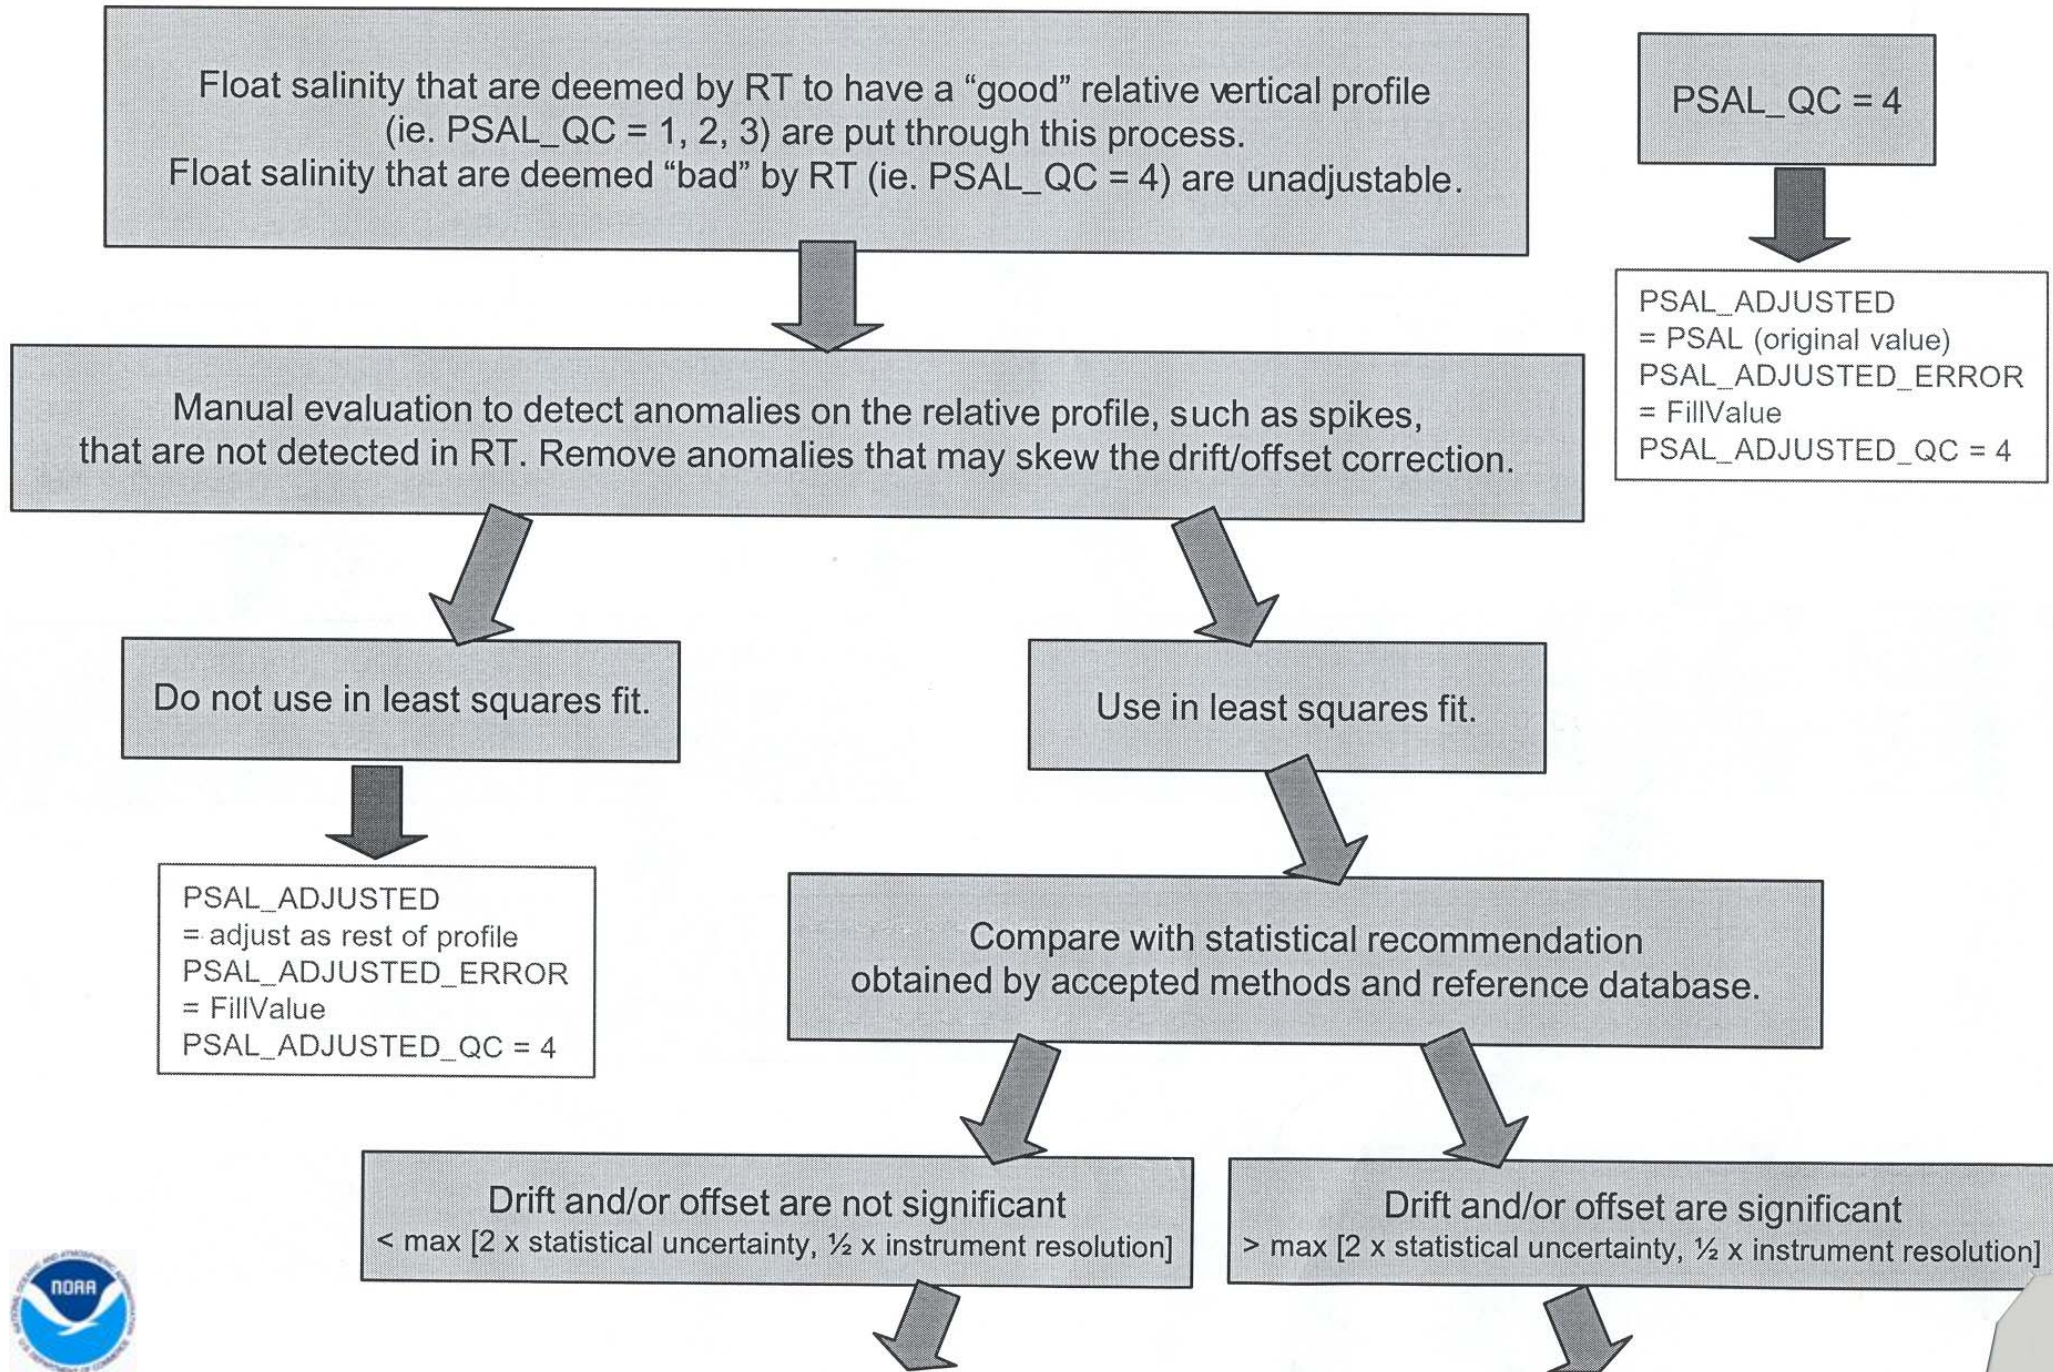

The Argo Information Centre is a source of information about the development and performance of the global array and the national programmes that contribute to it. The final repository for Argo data is with the US National Oceanographic Data Center (NODC) They will also distribute Argo data on CDs so as to permit Argo data use by groups without reliable or low cost internet access.

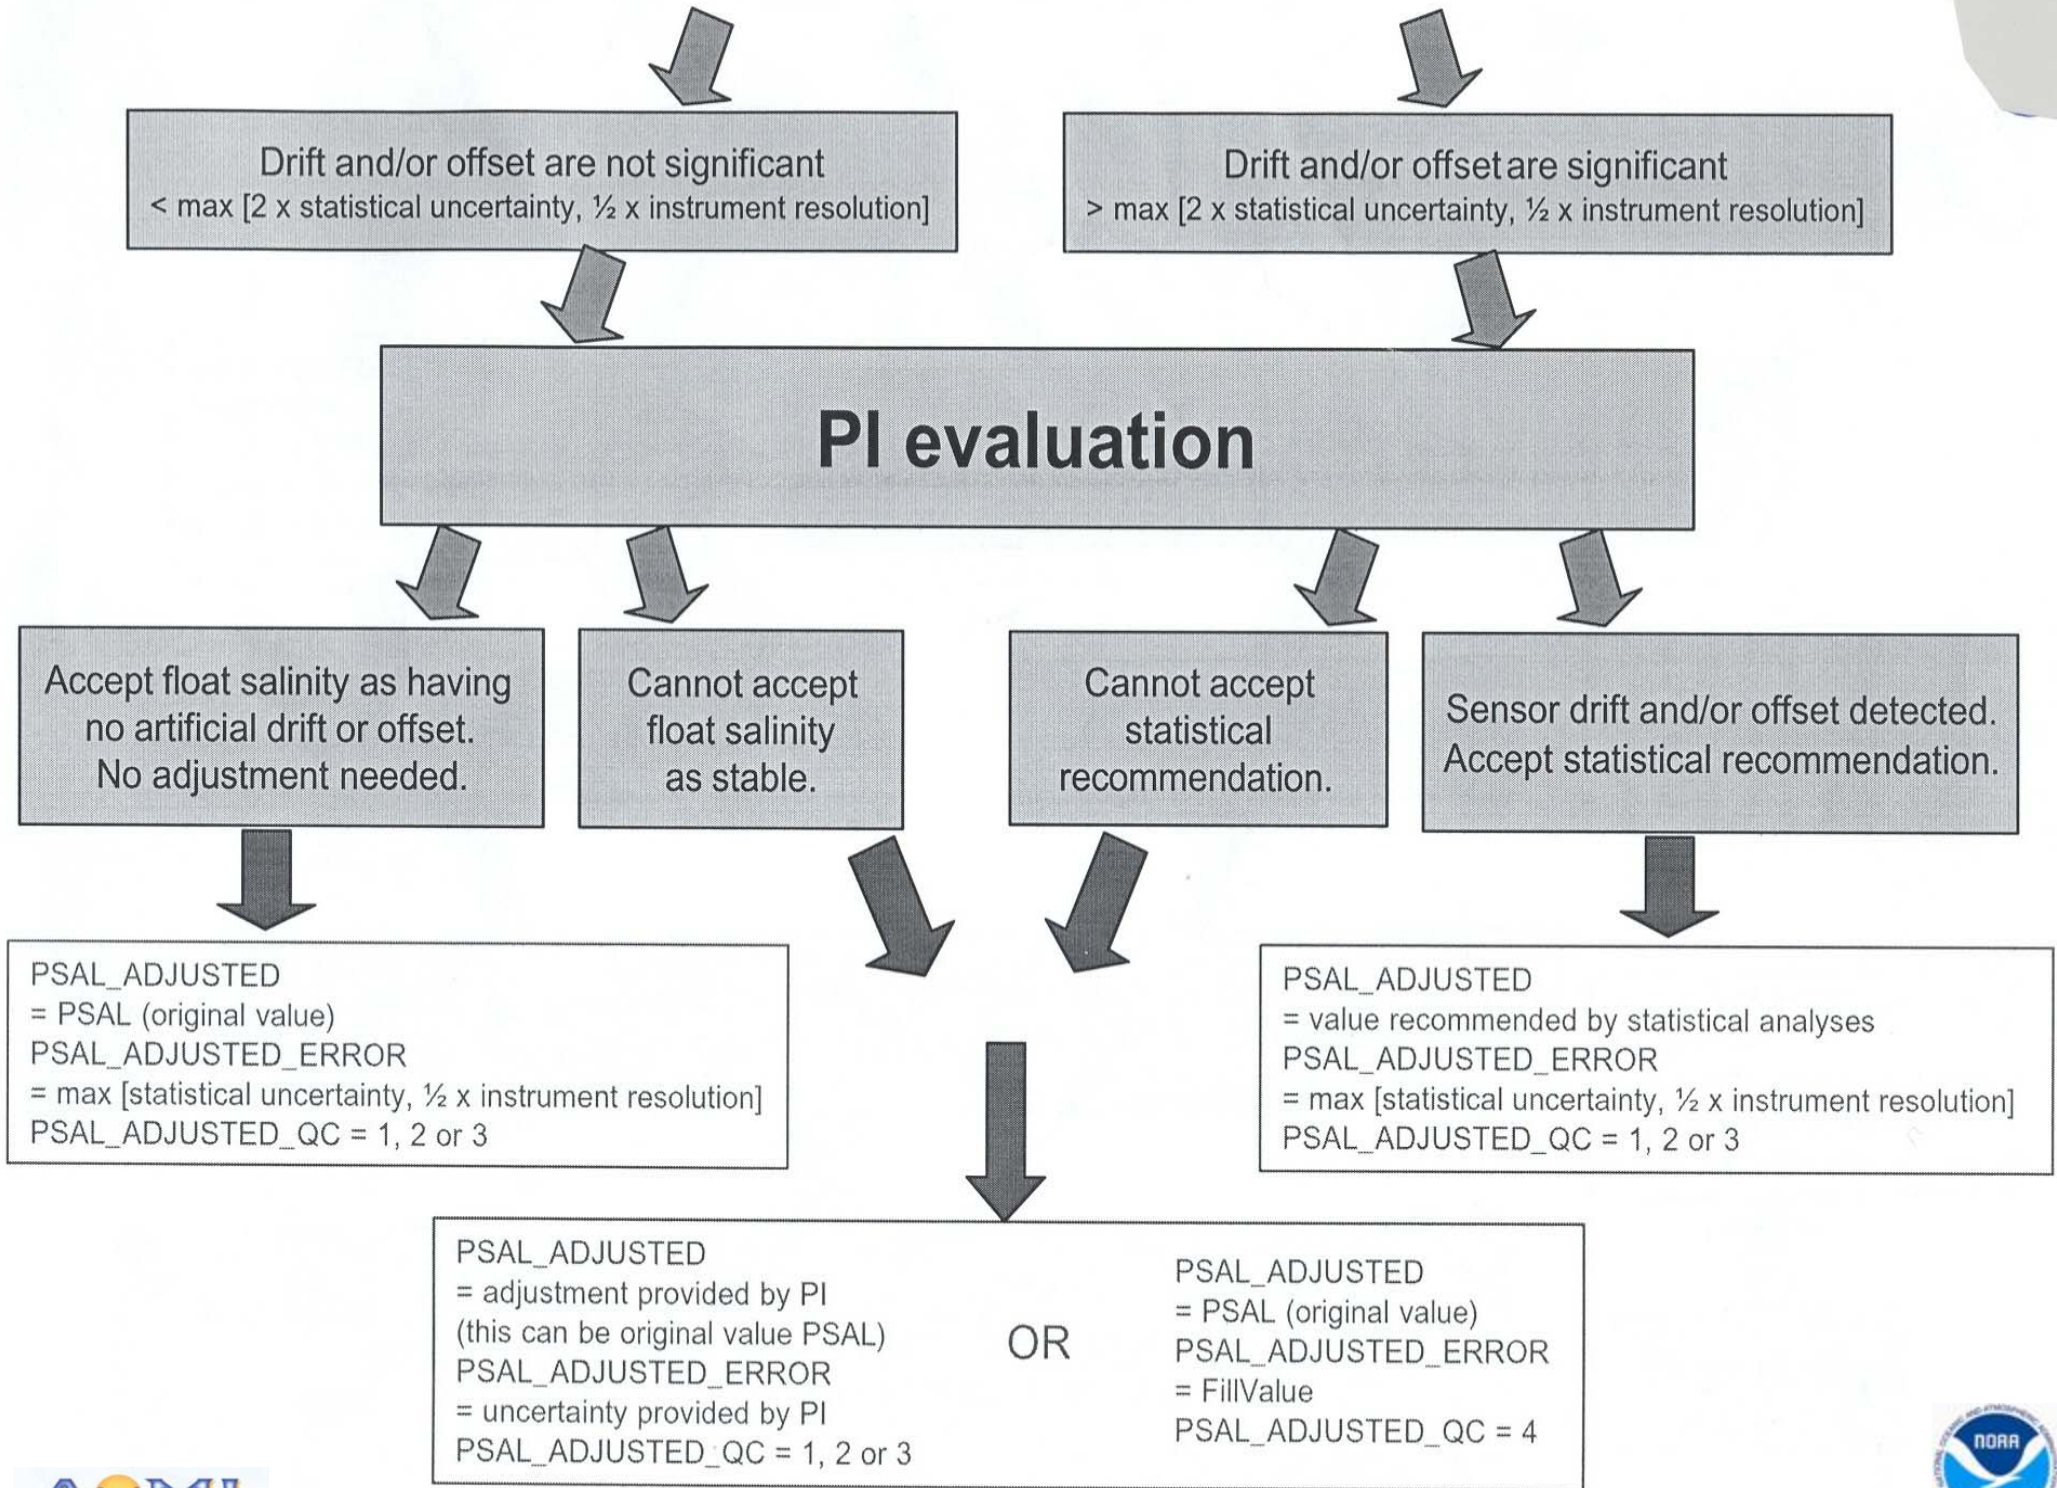

Argo Data Processing System Data Flow

Argo salinity artificial drift & offset QC procedures

A beginners' guide to accessing Argo data

John Gould – Argo Director

Argo collects salinity/temperature profiles from a sparse (average 3° x 3° spacing) array of robotic floats that populate the ice-free oceans that are deeper than about 2000m. They also give information on the surface and subsurface currents. Each profile is made up of about 200 data points. The first Argo floats were deployed in 2000 and the array will be complete in 2006/7. Argo data are made available to users quickly and free of restriction

The following document is a first draft for a brief user guide to the Argo data system. This is intended to describe to Argo users

- (i) what they should expect from Argo data (real-time and delayed mode streams) and
- (ii) how to find it.

Complete documentation of the Argo data system is contained in the "Argo Data Management Handbook" and "Argo Real-time Quality Control Tests Procedures", both available at http://www.coriolis.eu.org/cdc/argo_rfc.htm . Feedback from Argo users will be very valuable as we implement and test the remaining parts of Argo's data management system. Specifically, comments in the following areas are especially appreciated and should be sent to argo@ucsd.edu :

1. For users requiring real-time data (within about ~24 hours of measurement):

- Are there inconsistencies between Argo's specified real-time QC tests and what is found in the data files (GTS or Global data Centres)?
- Are there formatting problems in the GDAC netcdf files, with respect to the specifications in the Argo Data Management Handbook.
- Are there additional or better (fully automated) real-time QC tests that should be applied ? (For example it has been noted that a range check on pressure is needed).
- Is an automated estimate of salinity sensor drift (presently only in delayed mode data) needed?

2. For users requiring near real-time data, but on a time scale of several days or longer:

- Some DACS (e.g. US Argo DAC) are presently implementing visual profile inspection in near real-time. It is unlikely that this will be done by all national DACS unless there is a strong requirement expressed for an intermediate quality dataset (better quality than real-time, faster than delayed-mode). Is there such a requirement?

3. For users requiring scientific quality data (delayed-mode).

- At present, only about 20% of Argo profiles are available as delayed mode data (i.e. netcdf filename begins with D), and the delayed-mode system is still under

Area of interest of the institutes participating in Regional DACs implementation
