# Development of Tropical Cyclone Rainfall Climatology and Persistence (R-CLIPPER) Model

Frank Marks and Gretchen Kappler

NOAA/AOML/HRD

Mark DeMaria

NOAA/NESDIS/ORA

## INTRODUCTION:

- ◆ Tropical cyclones (TC) pose significant quantitative precipitation forecast (QPF) problem as evidenced by tragic loss of life and property from rain in Hurricanes Mitch (1998), Floyd (1999), and TS Allison (2001).
- ◆ Over last 30 years majority of TC-related deaths are caused by flooding (Rappaport 2000).
- ◆ Threat of flooding is a function of rain rate (R) and duration, making storm size (D) and motion (Vs) critical parameters.
- ◆ Enhanced rainfall due to orographic forcing and/or interactions with mid-latitude frontal boundaries increase threat of flooding.

- ◆ QPF limited by complexity of precipitation processes and lack of microphysics data.
- ◆ Improved QPF, particularly in TCs, is a primary objective of U. S. Weather Research Program (USWRP).

- ◆ **w drafts are small** (3 km), **relatively weak** ( $10\% > \pm 6.5 \text{ ms}^{-1}$ ;  $1\% > \pm 10.5 \text{ ms}^{-1}$ ), with 3 times more updrafts than down.
- ◆ **R cores are small** (50% diameters  $> 3.7 \text{ km}$ ) and **short-lived** (10% durations  $> 8 \text{ min}$ ) covering only **10%** of storm rain area. **90%** of rain **area** is stratiform.
- ◆ Yet, **stratiform rain** makes up **~50%** of total rain from TC.
- ◆ However, TC vortex structure dynamically constrains smaller scale circulations that confound better QPF.

- ◆ Over open water simplest TC QPF is a climatology and persistence (CLIPER) model that predicts peak storm total rain ( $R_{\max}$ ) as:
 
$$R_{\max} = RDV_s^{-1}$$
 integral of R along line (D) with  $V_s$ .
- ◆ Originated in late 1950s as Kraft's "rule of thumb" where:
 
$$R_{\max} = 130.8 V_s^{-1}$$
 where  $R_{\max}$  in cm,  $V_s$  in  $m\ s^{-1}$ , and climatological  $R=0.98\ cm\ h^{-1}$  and  $D=500\ km$ .
- ◆ Tropical Rainfall Potential (TRaP) (Ferraro et al 1998) uses similar approach, but with satellite R-estimates projected along track
- ◆ Note these techniques have no adjustments for storm intensity, topography, or other parameters.

- ◆ Problem is **sensitivity to assumptions of R, D, and  $V_s$**  which come from TC climatology. Relatively good estimates of D and  $V_s$  climatology are available globally.

- ◆ Problem is **sensitivity to assumptions of  $R$ ,  $D$ , and  $V_s$**  which come from TC climatology. Relatively good estimates of  $D$  and  $V_s$  climatology are available globally.

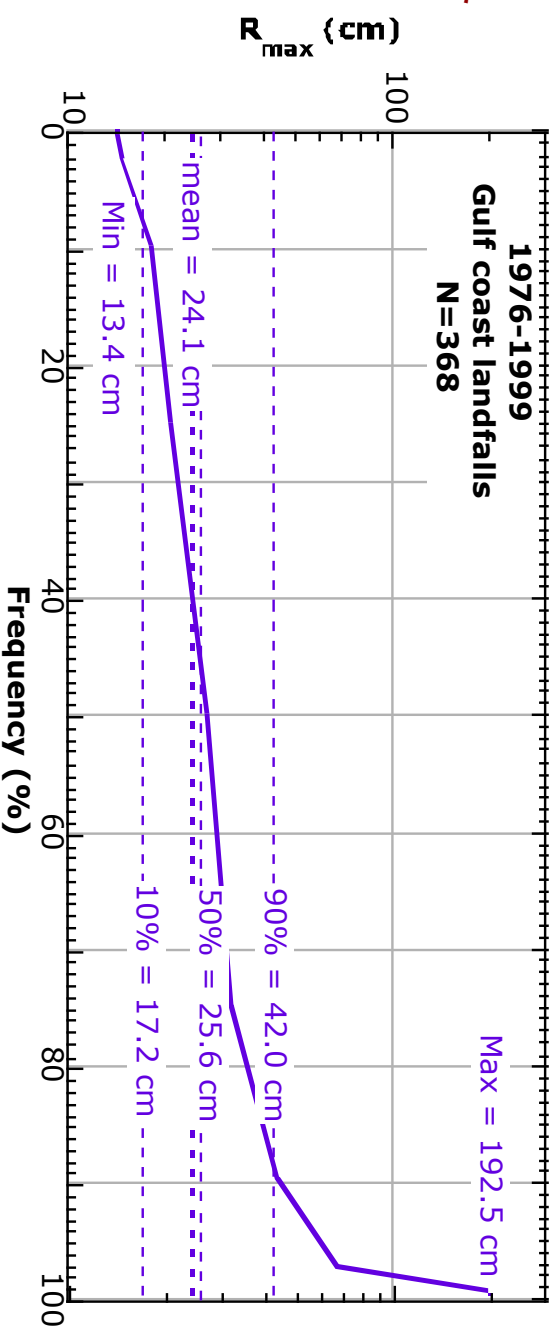

Sensitivity of  $R_{max}$  to  $V_s$  holding  $\bar{R}$  and  $D$  fixed for all Gulf landfalls 1976-1999

- ◆ Problem is **sensitivity to assumptions of  $R$ ,  $D$ , and  $V_s$**  which come from TC climatology. Relatively good estimates of  $D$  and  $V_s$  climatology are available globally.

Sensitivity of  $R_{max}$  to  $V_{sr}$  holding  $\bar{R}$  and  $D$  fixed for all Gulf landfalls 1976-1999

- ◆ Major stumbling blocks are: (1) use of mean  $R$  to represent  $R$  distribution (poor measure of non-normal distribution); and (2) lack of a comprehensive TC  $R$  climatology to define the PDF of  $R$  and mean  $R$ .

- ◆ Problem is **sensitivity to assumptions of  $R$ ,  $D$ , and  $V_s$**  which come from TC climatology. Relatively good estimates of  $D$  and  $V_s$  climatology are available globally.

Sensitivity of  $R_{max}$  to  $V_s$  holding  $\bar{R}$  and  $D$  fixed for all Gulf landfalls 1976-1999

- ◆ Major stumbling blocks are: (1) use of mean  $R$  to represent  $R$  distribution (poor measure of non-normal distribution); and (2) lack of a comprehensive TC  $R$  climatology to define the PDF of  $R$  and mean  $R$ .
- ◆ Estimates of  $R$  distribution based on radar (WSR-88D) and satellite microwave remote sensors offer promising avenues to develop  $R$  climatology.

- ◆ **OPPORTUNITY:**
  - ◆ Develop R climatology in TCs regionally and **globally**
  - ◆ Develop methodology to validate model forecasts.
- ◆ **DATA and METHOD:**
  - ◆ Instantaneous R-estimates from TRMM Microwave Imager (TMI) and Precipitation Radar (PR). **Strength is global coverage with single instrument.**
  - ◆ Hourly R-estimates from gauges. **Strength is high temporal resolution over long time.**

### Hurricane Danny\*

\* Rainfall totals for each state are comprised of observations for only the days listed for each state in the table at right

AL: July 20-23 #
FL: July 17-21 @
GA: July 21-24
LA: July 17-21
MS: July 17-22
NC: July 22-25
SC: July 22-25
VA: July 22-25

TRMM Descending Orbits

14:16	12:44	11:13	09:42	08:10
10324	10323	10322	10321	10320

- GOAL:**
- ◆ Improve understanding of tropical cyclone (TC) rainfall (R) by developing a rain climatology of TCs, **globally**,
  - ◆ Develop a methodology to improve forecasting of TC rain distributions.

**DATA:**

- ◆ R estimates from TMI version 5 for **245** storms from December 1997 to December 2000, globally, yielding **2121** events (observations), in TCs ranging from TD to category 5 intensity.

*1998-2000 TMI events by Intensity*

<u>Storm Intensity</u>	<u>Events</u>	<u>%</u>
TD/TS	1361	64
Category 1-2	548	26
<u>Category 3-5</u>	<u>212</u>	<u>10</u>
<b>Total</b>	<b>2121</b>	

- ◆ 560,000 hourly rain gauge estimates in 46 landfalling hurricanes in the U. S. from 1948-2000

## METHOD (continued):

- ◆ TMI passive microwave radiometer at 10.7, 19.4, 21.3, 37, and 85.5 GHz over a 758.5 km swath with ~5 km resolution. Surface rain (R, mm h<sup>-1</sup>) estimates from TB.

- Analysis domain:**
- storm-centered annuli
  - 50 10-km wide
  - 4 quadrants

## METHOD (continued):

- ◆ TMI passive microwave radiometer at 10.7, 19.4, 21.3, 37, and 85.5 GHz over a 758.5 km swath with ~5 km resolution. Surface rain (R, mm h<sup>-1</sup>) estimates from TB.

- Analysis domain:**
- storm-centered
  - 50 10-km wide annuli
  - 4 quadrants

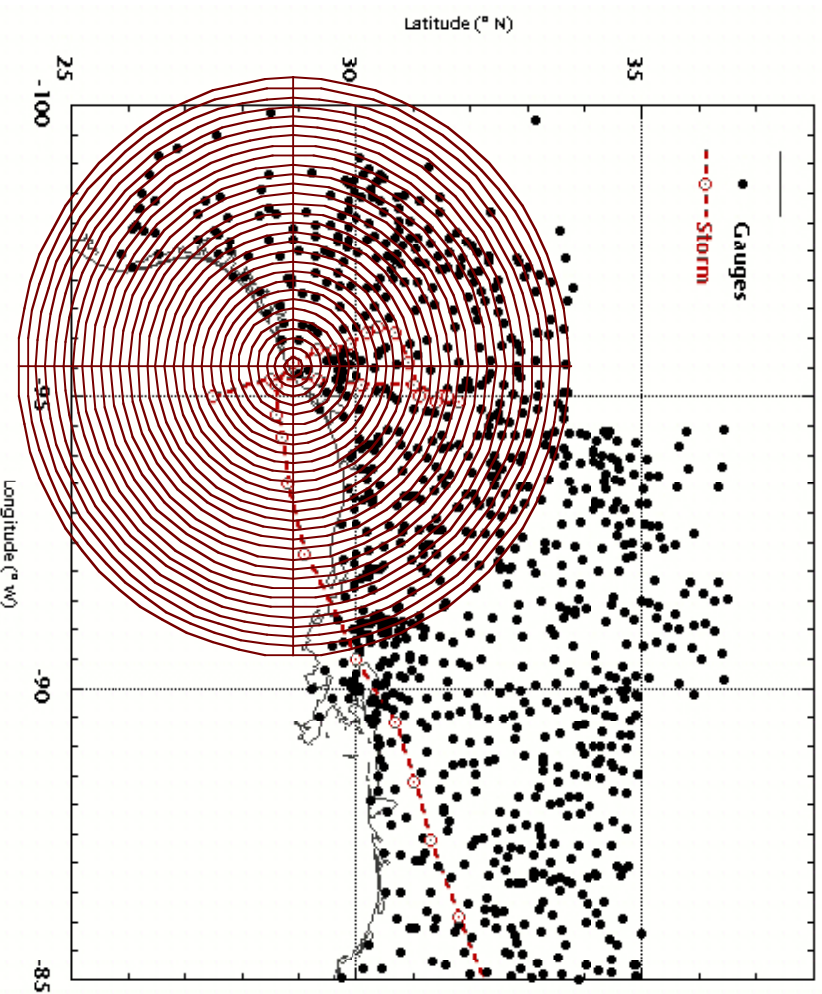

# METHOD (continued):

- Analysis domain:**
- storm-centered
  - 50 10-km wide annuli

## METHOD (continued):

- Analysis domain:**
- storm-centered
  - 50 10-km wide annuli

- ◆ Distribution of R examined as a function of intensity.
- ◆ PDF of R computed for 10 km radial bands in 1 dBR (10  $\log_{10}R$ ) steps from 0.3-300 mm  $h^{-1}$  (-5 to 25 dBR).
- ◆ Stratified by intensity and motion, to compare to radar and model estimates.

## RESULTS:

- ◆ Comparison of TMI and gauge to TC R probability distributions by Miller (1958) and Frank (1977) shows fairly good agreement.
- ◆ Comparison of TMI with recent WSR-88D and recent gauge estimates shows very good agreement.

# R-CLIPER Model (Rain Gauge vs TMI Version)

(Rain gauge data for storms within 6 h of landfall)

# R-CLIPPER Generalization using TMI Data

- ◆ Gauge data insufficient to stratify by intensity
  - ◆ Gauge R-CLIPPER forecasts depend only on track
- ◆ Use TRMM data to determine rain rate versus intensity
  - ◆ Replace gauge R with TRMM R.
  - ◆ TRMM R-CLIPPER depend on track and intensity.

## TMI R-CLIPPER

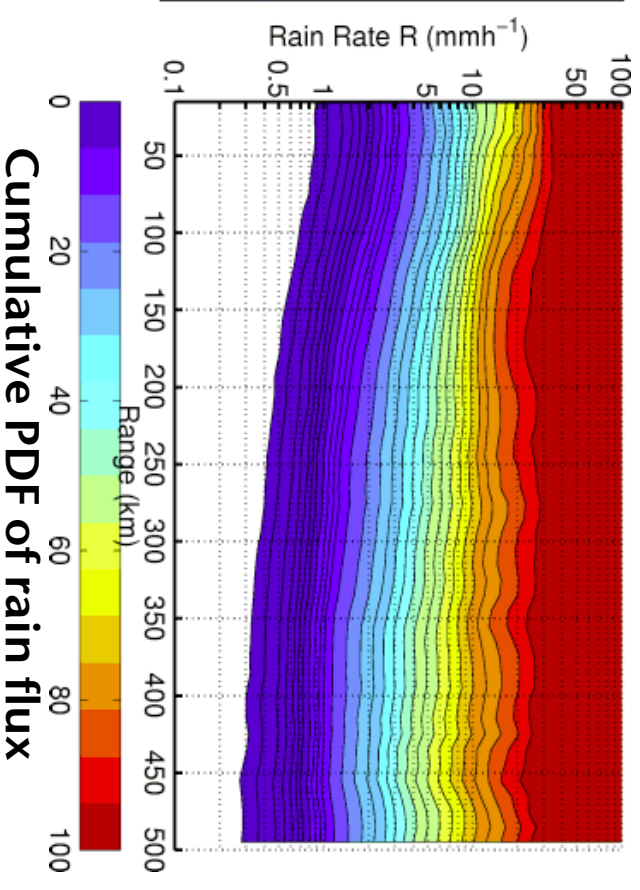

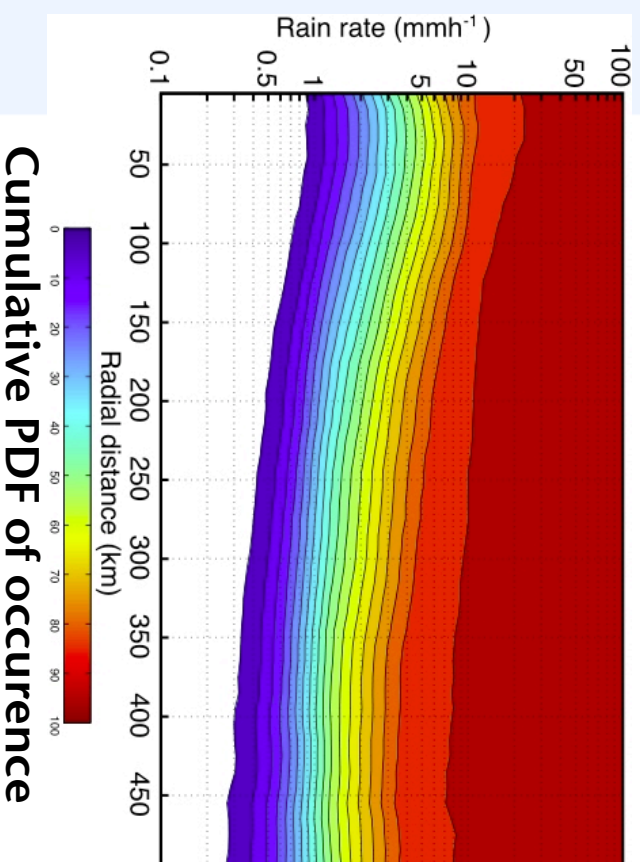

- ◆ Radial distribution of R realistic, with peak  $\sim 3.9$  mm h<sup>-1</sup> at 50 km and a drop below 1 mm h<sup>-1</sup> by 350 km.
- ◆ R near center increases with intensity from 3 mm h<sup>-1</sup> for TD/TS, to 7.2 mm h<sup>-1</sup> for hurricanes, to 12.5 mm h<sup>-1</sup> for major hurricanes.
- ◆ Radius of maximum R decreases with storm intensity from 60 km for storms, to 45 km for hurricanes, to 28 km for major hurricanes.

## TMI R-CLIPPER

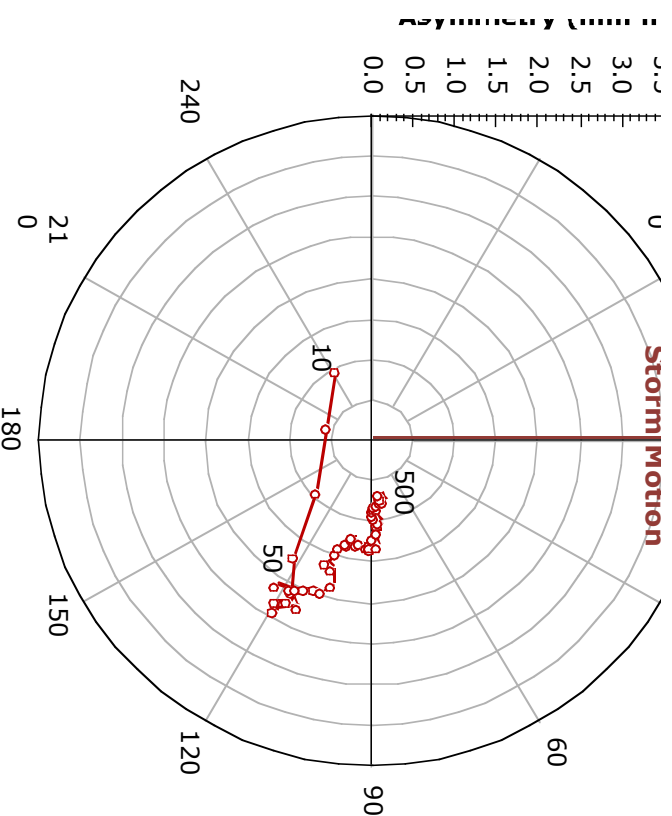

- ◆ TMI has added benefit of providing  $P(R)$  with uniform spread over 500 km indicating that  $R > 20 \text{ mm h}^{-1}$  occurs at all ranges.
- ◆ Largest probability of  $R > 10 \text{ mm h}^{-1}$  occurs at ranges  $< 100 \text{ km}$ . Most probable  $R > 100 \text{ km}$  is  $1 \text{ mm h}^{-1}$ .
- ◆  $RP(R)$  shows contribution to total  $R$  flux at ground. Indicates that  $R > 10 \text{ mm h}^{-1}$  contributes most to flux  $< 250 \text{ km}$ ,  $> 300 \text{ km}$  majority of flux from  $R < 5 \text{ mm h}^{-1}$ .

# TMI R-CLIPPER

- ◆ Also can produce asymmetry.
- ◆ Major asymmetry just outside range of maximum R. Magnitude of R asymmetry is 50% of maximum R.
- ◆ Over all basins and intensities, major asymmetry to the right of track, and slightly to the rear.

## Current TRMM R-CLIPPER

$$\begin{aligned} \text{Functional Form: } R(r) &= (R_0) + (R_m - R_0)\left(\frac{r}{r_m}\right) \quad r < r_m \\ &= R_m \exp\left(-\frac{(r - r_m)}{r_e}\right) \quad r > r_m \end{aligned}$$

Free parameters  $R_0$ ,  $R_m$ ,  $r_m$ ,  $r_e$  are functions of max winds

# R-CLIPPER Forecast for Erin 2001

AL083001 090418 ERIN

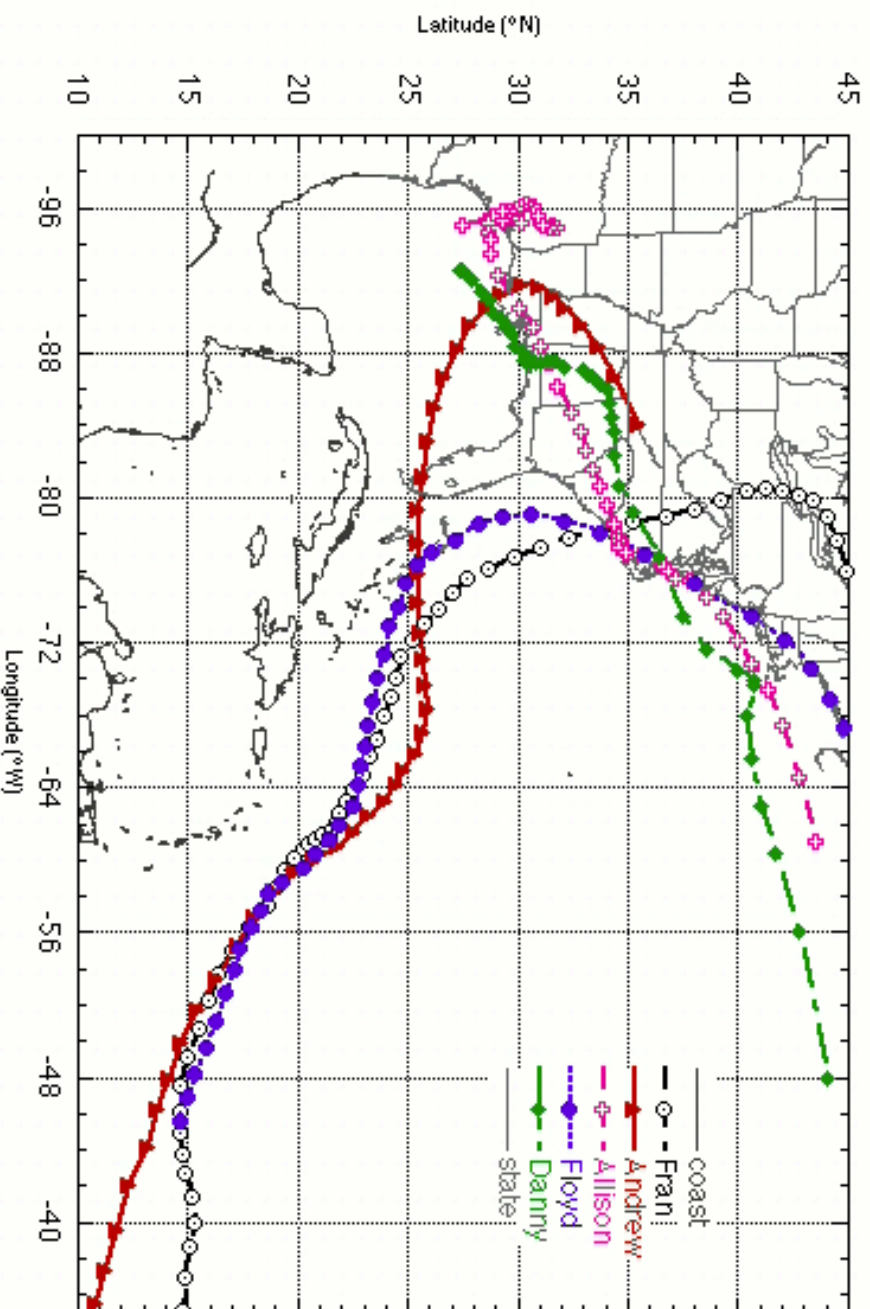

**R-CLIPPER Accumulated along 72 h NHC Track Forecast for Erin (4 Sept. 2001 18 UTC)**

# DIAGNOSTICS

- ◆ Plans call for diagnostics run on 5 cases.
- ◆ Validate storm total rainfall and 24-h total rain.

# R-CLIPER for

## Where Do We Go From Here?

- ◆ R-CLIPPER will provide a benchmark for evaluation of other more-general QPF techniques.
- ◆ Evaluate the R-CLIPPER forecasts run on a number of past storms to provide some statistics on model performance and to develop different data products useful to hurricane specialists.
- ◆ Compare R-CLIPPER forecasts with 6-h areal average rainfall amounts on a  $1^{\circ} \times 1^{\circ}$  grid, which is what HPC uses.
