Romanov E. V., Bach P., Rebik S. T., Le Turc A. & Séret B. 2013. — First pelagic record of the velvet dogfish *Zameus squamulosus* (Günther, 1877) (Squaliformes) from the southwestern Indian Ocean and some notes on its regional distribution. *Zoosystema* 35 (1): 11-23.
<http://dx.doi.org/10.5252/z2013n1a2>

ABSTRACT

A pelagic record of a rare deep-water shark, the velvet dogfish *Zameus squamulosus* (Günther, 1877), is described from the southwestern Indian Ocean. This is the first pelagic record from the western Indian Ocean and the eleventh published record of this species from the entire basin. Together with non-published records from museums and online databases the number of verified Indian Ocean records of this species currently exceeds 50 individuals. *Zameus squamulosus* is a benthopelagic species usually occurring on the slopes of the continents and in mid-ocean oceanic ridges, between 400 and 1450 m depth, but it makes rare incursions in open water to the limits of the epipelagic zone.

RÉSUMÉ

Première observation pélagique d'un requin-grogneur velouté, *Zameus squamulosus* (Günther, 1877) (Squaliformes), de l'océan Indien sud-occidental et quelques notes concernant sa distribution régionale.

La présence en milieu pélagique d'une espèce rare de requin de profondeur, le requin-grogneur velouté *Zameus squamulosus* (Günther, 1877), est décrite dans le sud-ouest de l'océan Indien. Il s'agit de la première signalisation de cette espèce en milieu pélagique dans l'océan Indien occidental, et de la onzième dans le bassin entier. En comptant les signalisations non publiées à partir des musées et les bases de données en ligne, les signalisations avérées de cette espèce dans l'océan Indien dépassent les 50 individus. *Zameus squamulosus* est une espèce benthopélagique : elle fréquente habituellement les pentes des continents et les dorsales océaniques, entre 400 et 1450 m de profondeur ; elle effectue aussi de rares incursions en pleine eau, à la limite inférieure de la zone épipélagique.

INTRODUCTION

The squaloid shark *Zameus squamulosus* (Günther, 1877) is a deep-water species, encountered in the benthic and sometimes in the pelagic environment along continental margins of tropical and temperate waters in the Atlantic and Pacific (Compagno 1984; Wetherbee & Crow 1996). Its distribution and occurrence in the Indian Ocean are still obscure. Only few published records of *Z. squamulosus* are known from the undersea ridges of the southern tropical Indian Ocean (Scherbachev et al. 1982). Other records, although lacking geo-referencing precision, are attributed to continental slope areas of South Africa, Australia and Java (Indonesia) (Bass et al. 1976; Last & Stevens 1994, 2009; White et al. 2006). One individual was recently collected at

a landing site in Cochin, India (Akhilesh et al. 2011).

Despite its global distribution, biology and habitat of the velvet dogfish are still poorly known: it is listed as “data deficient” on the IUCN Red List of Threatened Species (Burgess & Chin 2006). Therefore information presented in this note is important for the understanding of this species’ ecology.

Here we describe the first record of *Z. squamulosus* from the pelagic zone of the tropical southwestern Indian Ocean and present a further nine recent records from the demersal environment. We discuss regional species distribution based on: 1) published data; 2) museum collection inventories; and 3) online sources. Finally, we debate the reliability of information from internet portals.

FIG. 1. — Individuals of *Zameus squamulosus* (Günther, 1877) caught in the pelagic and demersal environment: **A**, MNHN 2012-0188, female (672 mm TL) caught on a pelagic longline set on 25 May 2011 in the southwestern Indian Ocean (black bar at the ruler is equal to 5 cm); **B**, female caught on a demersal longline set on 5 March 2008 in the southeastern Indian Ocean (see Table 2 for details) (ruler length is 30 cm).

MATERIAL AND METHODS

A female of *Zameus squamulosus* (672 mm total length, TL; 640 mm fork length, FL) (Fig. 1A) was caught on 25 May 2011 on a tuna longline set by the commercial fishing vessel *Fournaise* during a research cruise in the framework of the PROSPER Project. E. V. Romanov and A. Le Tuc were onboard during the capture, collected accurate fishing and environmental data and preserved the specimen. Approximate capture position ($23^{\circ}17'S$, $52^{\circ}17'E$, mid-point of the pelagic longline gear) is in the proximity of the southwestern limit of the Exclusive Economic Zone of Reunion Island, France (Fig. 2). The research pelagic drifting longline used in this set consists of deep sections (12 hooks between floats, maximum fishing depth [MFD] 215–323 m),

very deep sections (24 hooks between floats, MFD 439–534 m) and surface sections (six hooks between floats, MFD 67–146 m). The shark was caught on a very deep section of the gear by the fifth hook baited with squid, *Illex argentinus* (Castellanos, 1960), at the estimated depth 290–300 m. MFD and estimated hook depth were calculated using corrected catenary curve geometry (Bach *et al.* 2009) with COPAL software v. 2.5.3 (Bach *et al.* 2011), and adjusted using direct measurements of section mid-point depth with temperature-depth recorders (TDR).

Sea surface temperature (SST) measured during vertical profiling of the water column with TDR before and after the fishing operation ranged within 25.9 – 26.2 °C, T °C at a depth of 300 m varied from 15.4 to 16.1 °C. Ocean floor topography

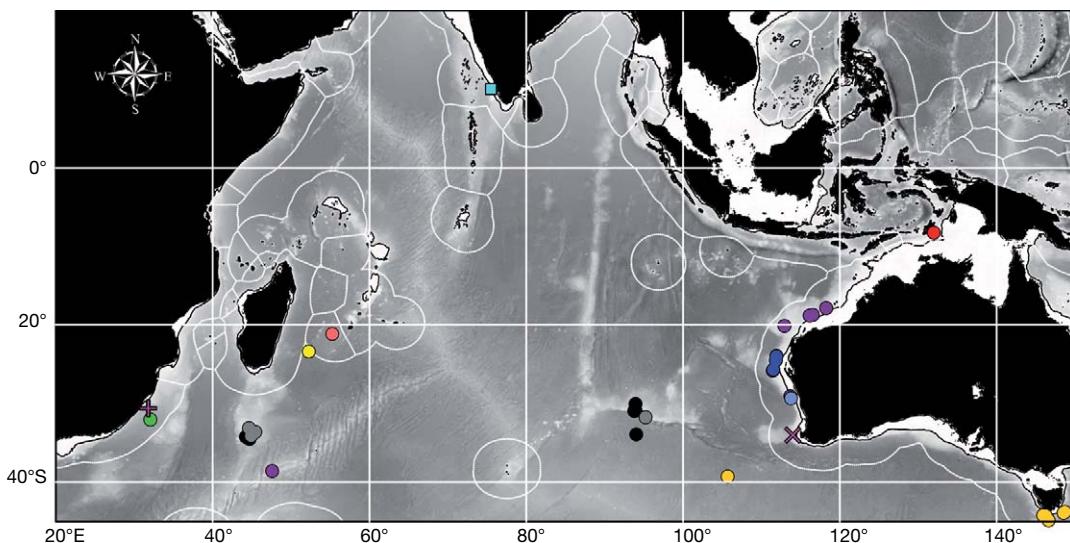

Fig. 2. — Geographic position of *Zameus squamulosus* (Günther, 1877) from the Indian Ocean (Table 2): **Pelagic** records: yellow dot (this study) and orange dots (CSIRO); **Demersal** records: black dots (YugNIRO, this study), grey dots ZM MGU (Scherbachev et al. 1982), pink dot (MNHN), purple dots (CSIRO), blue (AM), light blue (MV), green (Iziko SAM), red dot (IRD bottom survey), please note superposition of several CSIRO, AM and MV records; **Sperm whale** stomach records: straight cross is Bass et al. (1976) and oblique cross is WAM; **Bright blue** square is landing site recovery (Akhilesh et al. 2011). Approximate position of the 200-mile Exclusive Economic Zones (EEZs) of coastal states (dotted line) and 200 m isobath are shown. Coastline and bathymetry data are from GEBCO (2010), EEZs are from VLIZ (2011).

data taken from the GEBCO database (GEBCO 2010) suggests that the fishing gear was deployed and drifted over a deep-water canyon (bottom depths 5000–5400 m) surrounded by deep-water seamounts (minimum depth 3500–3800 m), and by an abyssal plain of 4500–4900 m deep.

The shark was frozen and stored for 30 days before examination. The specimen was deposited in the collections of the Muséum national d'Histoire naturelle, Paris (catalogue number MNHN 2012-0188).

Measurements were taken to the nearest mm following Bass et al. (1976) and Compagno (1984) approaches and expressed as percentage of TL. Total length used for calculation of body proportions was measured for “stretched” caudal fin as presented in Compagno (1984) in alternative to “natural” position as suggested by Bass et al. (1976). Denticles from left side of the trunk (Fig. 3A) were examined under a light microscope (Olympus SZ61 under $\times 45$ magnification) and photographed with digital camera Olympus SP510UZ resolution 7.1 Mpx.

Another eight specimens of this species were caught by demersal longlines during commercial fishing operations in the southern Indian Ocean in March–April 2008. Individuals were sampled and identified by S.T. Rebik as *Scymnodon obscurus* Vaillant, 1888 (a synonym of *Zameus squamulosus*) using keys in Compagno (1984) (Fig. 1B). Denticles from left side of the trunk were also photographed using a light microscope (Fig. 3B). Occurrence, fishing depth and some biological observations were recorded and used here to illustrate both spatial and vertical species distribution (Figs 2; 4).

One more individual (female, 710 mm TL) preserved in the MNHN collections (catalogue number MNHN 2007-1658, identified by B. Séret as *S. obscurus*) was caught on the slope of Reunion Island using a demersal longline baited with squid on 22 February 2005 by the commercial fishing vessel *Ludo* (Fig. 2).

The Indian Ocean area is considered here according to FAO definitions of fishing areas 51 and 57, with its western border off South Africa at 30°E and eastern border off Southern Australia at 150°E.

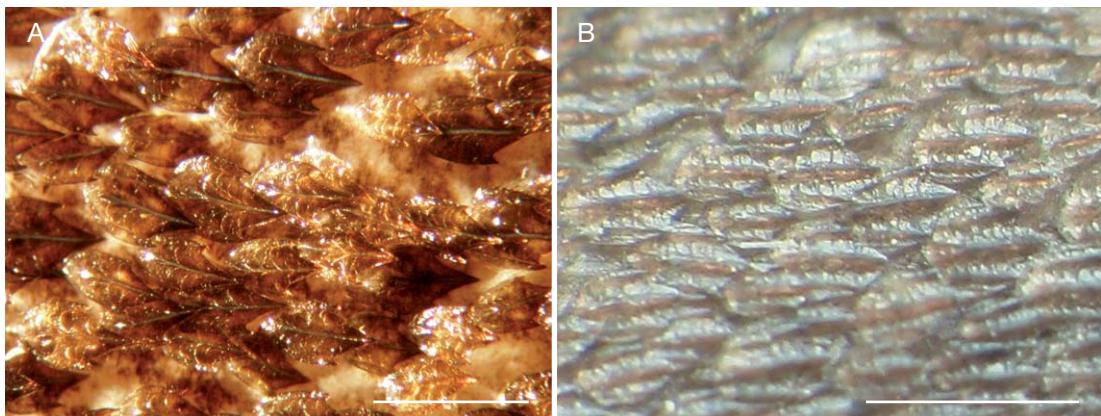

FIG. 3. — Dermal denticles from the trunk region of *Zameus squamulosus* (Günther, 1877) caught in the pelagic and demersal environment: **A**, MNHN 2012-0188, female, 676 mm TL; **B**, female from demersal zone of the southeastern Indian Ocean shown on the Figure 1B. Scale bar: 1 mm.

DISTRIBUTION. — Worldwide over continental slopes and undersea ridges in tropical and temperate waters.

DESCRIPTION

Individual caught in pelagic environment (MNHN 2012-0188) is a medium-sized, black-coloured shark with bright green eyes. It was alive at the time it was taken onboard but quickly died afterwards. Body proportions of our specimen are shown in Table 1. Dental formula: 27-27/21-21.

Our specimen well corresponds to the original description given by Günther (1877) and later by Yano & Tanaka (1984). Body measurements are within the ranges presented in other studies, except PP2, SVL (slightly higher than reported earlier) and trunk width (slightly lower) (Table 1). The latter could be explained by post-defrosting deformation.

DISCUSSION

To date, 10 individuals of this species are reported in the literature from the Indian Ocean region (Table 2). First record by Bass *et al.* (1976) who reported four semi-digested individuals taken from the stomach of a sperm whale *Physeter macrocephalus* harpooned 112 km southeast of Durban (Fig. 2). Consequently no exact data on both shark location and habitat depth were recovered. Another five individuals were caught by bottom trawls along deep-water ridges of the southern tropical Indian Ocean during Soviet research cruises in 1976-79 (Scherbachev *et al.* 1982). One more individual was recently recovered at the landing site in Cochin Fishing Harbour (India), but precise capture position is apparently unknown (Akhilesh *et al.* 2011) (Fig. 2; Table 2).

TABLE 2. — Details of capture positions of the Indian Ocean *Zameus squamulosus* (Günther, 1877) presented in Figure 2. Non geo-referenced occurrences are not mapped and not given here. Abbreviations: **TRAWB**, bottom trawl; **LLP**, pelagic longline; **SPN**, bottom /demersal longline; **SPW**, sperm whale *Physeter macrocephalus*; **TL**, total length; *, capture position was estimated from description available in the source, ** size range of five individuals stored under the same catalogue number.

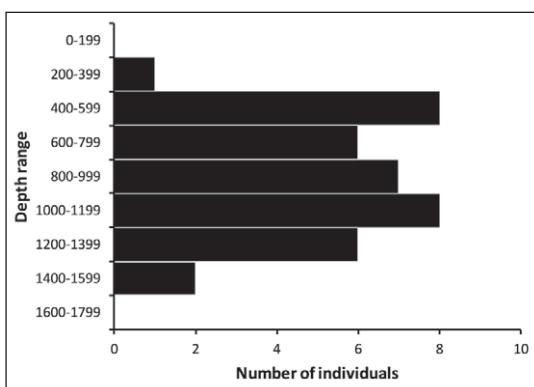

FIG. 4. — Depth distribution of *Zameus squamulosus* (Günther, 1877) with known capture depth recorded in the Indian Ocean ($n = 42$). For non-precise depth of capture, shallower depth in the range of values was used.

Last & Stevens (2009) mentioned captures of *Z. squamulosus* along the shelf of Western Australia by trawls and off Southern Australia by Japanese longliners in pelagic waters. Numbers of individuals caught and positions of capture were not presented in the source.

Similarly White *et al.* (2006) reported occurrences of this species in Indonesia (off western Java).

Direct correspondence with museums allowed us to obtain data on 35 records from the Indian Ocean (CSIRO, 31 ind.; Iziko SAM, 3 ind.; WAM, 1 ind.). Among these records twelve originated from pelagic gears, 22 were caught in the demersal environment, and one (WAM) was found in the stomach of a sperm whale (Fig. 2; Table 2).

Online resources were assumed to be a handy tool for fast and easy access to taxonomic and biogeographic information (Costello & Berghe 2006). Indeed internet portals appeared to be very useful to find occurrences, which otherwise would remain unknown/inaccessible for us. However we found that online portals handling taxonomic and fish biodiversity information (Discover Life, FishBase, GBIF, ITIS, OBIS, WoRMS) often maintain outdated taxonomic data. The species in question was commonly found either under synonymised names as *S. squamulosus* and *S. obscurus* or both were considered as separate valid species (Vanden Berghe 2007; Appeltans *et al.* 2011; Froese & Pauly

2011; GBIF 2011; Discover Life 2012; ITIS 2013). To some extent such a situation can be explained by the fact that the taxonomic status of this species has only been recently established (McEachran & Fechhelm 1998; Compagno 2003; Last & Stevens 2009).

Despite taxonomic uncertainties, we traced the number of unpublished records. Most of them originated from museum collections already available to us by direct correspondence (CSIRO, Iziko SAM). Additional records are demersal catches from Western Australia (OBIS: AM, 3 ind.; and MV 2 ind.) and southern Indonesia (off Tanimbar Islands) (OBIS, IRD KARUBAR cruise, 2 ind.) (Vanden Berghe 2007) (Fig. 2; Table 2).

The FishBase map (Froese & Pauly 2011) shows more Indian Ocean records for this species (both identified as *S. obscurus* and *Z. squamulosus*), however, links to published references or museum collections are not always evident for several mapped points, therefore their validity cannot be confirmed. Furthermore, some records of *S. obscurus* traced through FishBase and GBIF to specimens from collections of ZMH (e.g., ZMH 112266) should be attributed to other species and/or sampled in other oceans (Ralf Thiel [Curator Ichthyology, Biocenter Grindel und Zoological Museum University of Hamburg] pers. comm., 2011). In addition, capture positions provided by GBIF and OBIS for the same individuals (inventory numbers) from the collections of the Australian Museum and the Museum Victoria were different. Therefore, the reliability of online data sources for reporting of rare species distribution is still questionable as suggested by Eschmeyer & Fricke (2012).

Our records and earlier collected data show that *Z. squamulosus* is distributed within the subtropical area of the southern Indian Ocean from the African to the Australian coasts (Fig. 2). Only few records are from the tropics and only one individual is from the northern hemisphere (Fig. 2). Capture positions are usually associated with continental slopes and mid-ocean undersea ridges.

The majority of Indian Ocean records except our pelagic individual and twelve individuals from CSIRO were caught in demersal environment. Most of the fishes were taken between 400 and

1400 m depth; peak of occurrences is within the 1000–1200 m range (Fig. 4). Such a pattern suggests a benthopelagic life style of *Z. squamulosus* with regular excursions from the benthic to pelagic waters within the upper bathyal habitat.

Meanwhile, our pelagic capture reported here is not an exception. In the Atlantic and Pacific Ocean *Z. squamulosus* is considered as a pelagic species in some areas (Yano & Tanaka 1984; Compagno 1984). Numbers of pelagic records of this species have increased exponentially worldwide from single individuals some decades ago (Krefft 1980; Wetherbee & Crow 1996) to several dozens of individuals reported annually in recent years (Matsuhita & Matsunaga 2002; Dai *et al.* 2009; Zhu *et al.* 2012). Last & Stevens (2009) stated that pelagic records are more common than benthic ones off southern Australia. Such an increased number of recent occurrences cannot be explained only by expanded scientific observers' coverage of fishing operations and improved identification of specimens caught. The archive of high-quality long-term research data collected with pelagic longlines over all the Indian Ocean (Romanov *et al.* 2006) contains no records of this species in the pelagic environment from 1961 to 1989. We may be evidencing a long-term increase in abundance of this species similarly with other mid-sized oceanic predators like crocodile shark (Romanov *et al.* 2008), bramids and gempylids (Polovina *et al.* 2009) in response to the depleted state of large-sized predators or competitors (mesopredator-release effect) (Baum & Worm 2009; Ferretti *et al.* 2010).

At the same time, both pelagic and benthic records of *Z. squamulosus* are still rare over the vast area of the central and western Indian Ocean. Pelagic longline fisheries covering most of the surface of the tropical and temperate Indian Ocean developed an average fishing effort of almost 700 million hooks annually from 2000 to 2010 (Fonteneau 2010; Fonteneau pers. comm., 2012). Only thirteen pelagic individuals of this species recorded during the history of regional fisheries observations under such significant fishing effort suggests that epipelagic excursions should be considered rather as an exception than common habit.

The range of the TL of the Indian Ocean individuals reported in this note is within 415 and 900 mm. Four of eight individuals analysed in the field by STR exceeded the maximum reported length (TL) of 786 mm (Wetherbee & Crow 1996), and one exceeds the maximum length (TL) suggested by Last & Stevens (1994, 2009) (Tables 1; 2). Both sexes were present in catches; some individuals were mature. One gravid female (TL = 900 mm) caught on 17 March 2008 (Table 2) had two embryos at an advanced stage of development. Overall Indian Ocean records show dominance of females: 1.9:1.0, which however non-significantly deviate from 1:1 sex ratio ($\chi^2 = 3.125, p = 0.0771$).

The rarity of this species is an apparent consequence of a relatively low fishing effort within its principal depth distribution range and the scarcity of scientific observations in deep-water fisheries. However low fishing pressure is rather beneficial for the conservation of this species taking into account both the high longevity and slow reproduction rate characteristic of most deep-water chondrichthyans (Musick & Bonfil 2005).

Acknowledgements

We are thankful to the captain and the crew of F/V *Fournaise* for proper handling of our specimen during fishing operation and overall assistance during the research cruise. We acknowledge kind permission of the Government of Namibia to use occurrence data collected onboard Namibian-flagged F/V *Antillas Reefer*. Thanks are due to the captain and crew of F/V *Antillas Reefer* for their help rendered to STR during sampling and photographing. Our thanks to Mr Lausin Beboit, captain of F/V *Ludo*, for the collection and preservation of an individual of *Z. squamulosus* (MNHN 2007-1658).

Contributions of referees: S. Amir, P. Kyne and A. Ohler improved clarity and completeness of the paper.

Special thanks are due to Clément Martineau (ESA, Angers) for his help in microscopic photography of scales.

Alastair Graham (CSIRO), Sue Morrison (WAM), Michael Bougaardt (Iziko SAM), and Roger Bills (SAIAB, Grahamstown) provided data for specimens

stored in their respective museums. Particular thanks are offered to Dr Ralf Thiel, curator Ichthyology in ZMH, for precisions with species attribution and capture positions of sharks of the genus *Scymnodon* stored at ZMH collection.

Alain Fonteneau provided estimates of international pelagic longline effort in the Indian Ocean during 2006-2010.

We appreciate assistance with the English of the manuscript provided by Dr Marcelo de Carvalho and by Mr Alan Sharp.

PROSPER Project is funded by the Fonds Européen pour la Pêche (FEP).
