Hello again

Here are the 8 day data. The filenames aren't that informative but each image has a date in the title. The date is the middle of an 8-day window from which the data were averaged.

On 8-Aug you can see a glimpse of high chl (just NW of where 138W and 52N cross) in the region where a lot of drifters get deployed around 16-Aug and then voila there's very high chl on 24-Aug. My personal opinion is that, given this information and the time lags involved, it seems unlikely that the bloom was (entirely) generated by Fe fertilisation. What do others think?

I just realised my previous plots omitted lat-lon so I am attaching the monthly 4-panel again.

Regards
Pete

<rhamme@uvic.ca<mailto:rhamme@uvic.ca>> wrote:

Hi folks,

Just talked to someone at NOAA about the Argo drifters deployed as part of this project. They're drifters from AOML, not standard Argo floats. You can see the group of Argo drifters deployed near Haida Gwaii in these figures. Most of them are quite a lot farther offshore than I supposed they would be. As won't surprise you, AOML was not fully informed about the purpose of this project. They frequently work with citizen groups to

deploy drifters in areas where they do not have enough coverage. I believe they would rather strenuously object to being called collaborators in this "experiment".

cheers, Roberta
