I. INTRODUCTION

The primary objectives of the STACS program are to increase our understanding of the dynamics of the North Atlantic circulation and the role of ocean circulation in global climate, to develop the capability to monitor the climatically important processes, and to provide data needed in the development of the coupled ocean-atmosphere general circulation models to be used for global climate prediction. In particular, the mechanisms by which the ocean transports heat to balance the net radiation deficit at northerly latitudes are being studied.

The initial objectives of STACS (Molinari et al., 1985) were directed at the Florida Current, a flow which makes significant contribution to heat flux. After an intensive two-year observing program, we have the capability to monitor Florida Current transport without extensive ship-board observations. Data collected during this period are listed in Williams et al. (1983), Leaman and Vertes (1983), Vertes and Leaman (1984), and Ratnasamy et al. (1985). STACS efforts during 1984-1986 were directed toward studying the relationship of western boundary currents along the Antillean Archipelago and in the Caribbean Sea to the dynamics of the North Atlantic subtropical gyre and on meridional heat flux, while continuing the monitoring effort in the Florida Current at 27°N. STACS efforts during 1987-1988 continued the observational studies of western boundary currents, extending the study area southward to northern Brazil (4°N) in order to examine North Atlantic cross-equatorial fluxes of mass and heat. Data collected during these cruises are given in Wilburn et al. (1987a,b, 1988, and 1989).

During 1989 STACS observational efforts extended even farther east and south. During the February 1989 cruise the western half of a cross-Atlantic transect along 14.5°N was done (in cooperation with a German cruise which occupied the eastern half) in addition to observations of the western boundary currents between Barbados (13°N) and northern Brazil (4°N). This cruise was done in cooperation with Dr. Rana Fine's group from the University of Miami, and included freon measurements at the CTD-O₂ stations. STACS monitoring of the Abaco, Bahamas transect at 26.5°N continued. The August 1989 cruise extended south to the equator in the course of deploying a joint RSMAS/KIEL moored current meter array. Figures 1 and 2 show station locations for the February and August 1989 cruises, respectively. XBT data were generally collected along the entire cruise track, with CTD-O₂ and Pegasus stations taken where indicated.

II. DATA COLLECTION AND ANALYSIS

Data from STACS cruises conducted on the NOAA Ships ALBATROSS IV and MALCOLM BALDRIGE during two cruises—February and August 1989—are contained in this report. Table 1 shows the type of data collected on each cruise. Techniques used to reduce the Pegasus, CTD, and XBT data to final form are described below.

A. Pegasus Current Profiler

The Pegasus instrument is an acoustically-tracked, free-falling profiler of horizontal current components (Spain et al., 1981). A schematic of the Pegasus system is shown in Figure 3. The Pegasus instrument used by AOML consists of a hollow cylindrical metal tube with the electronics package

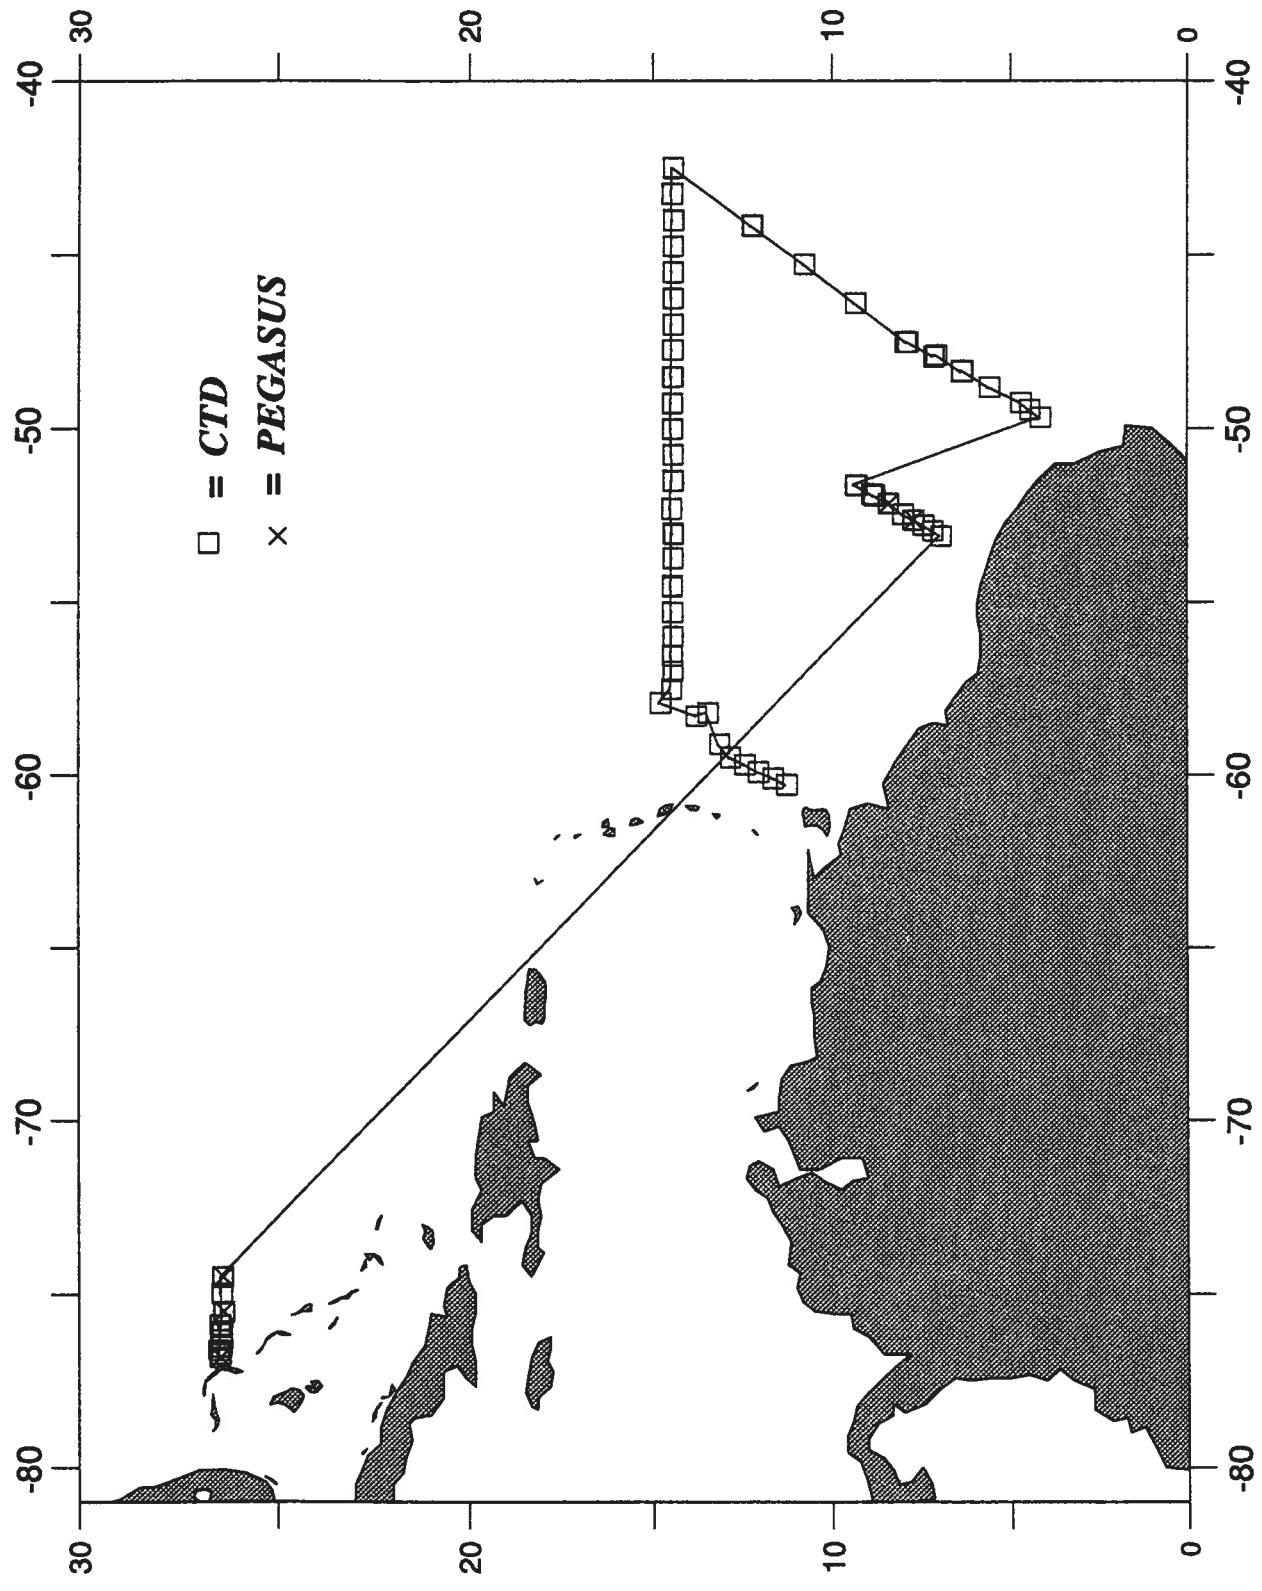

Figure 1. STACS cruise track for February 1989 showing CTD and Pegasus sampling stations.

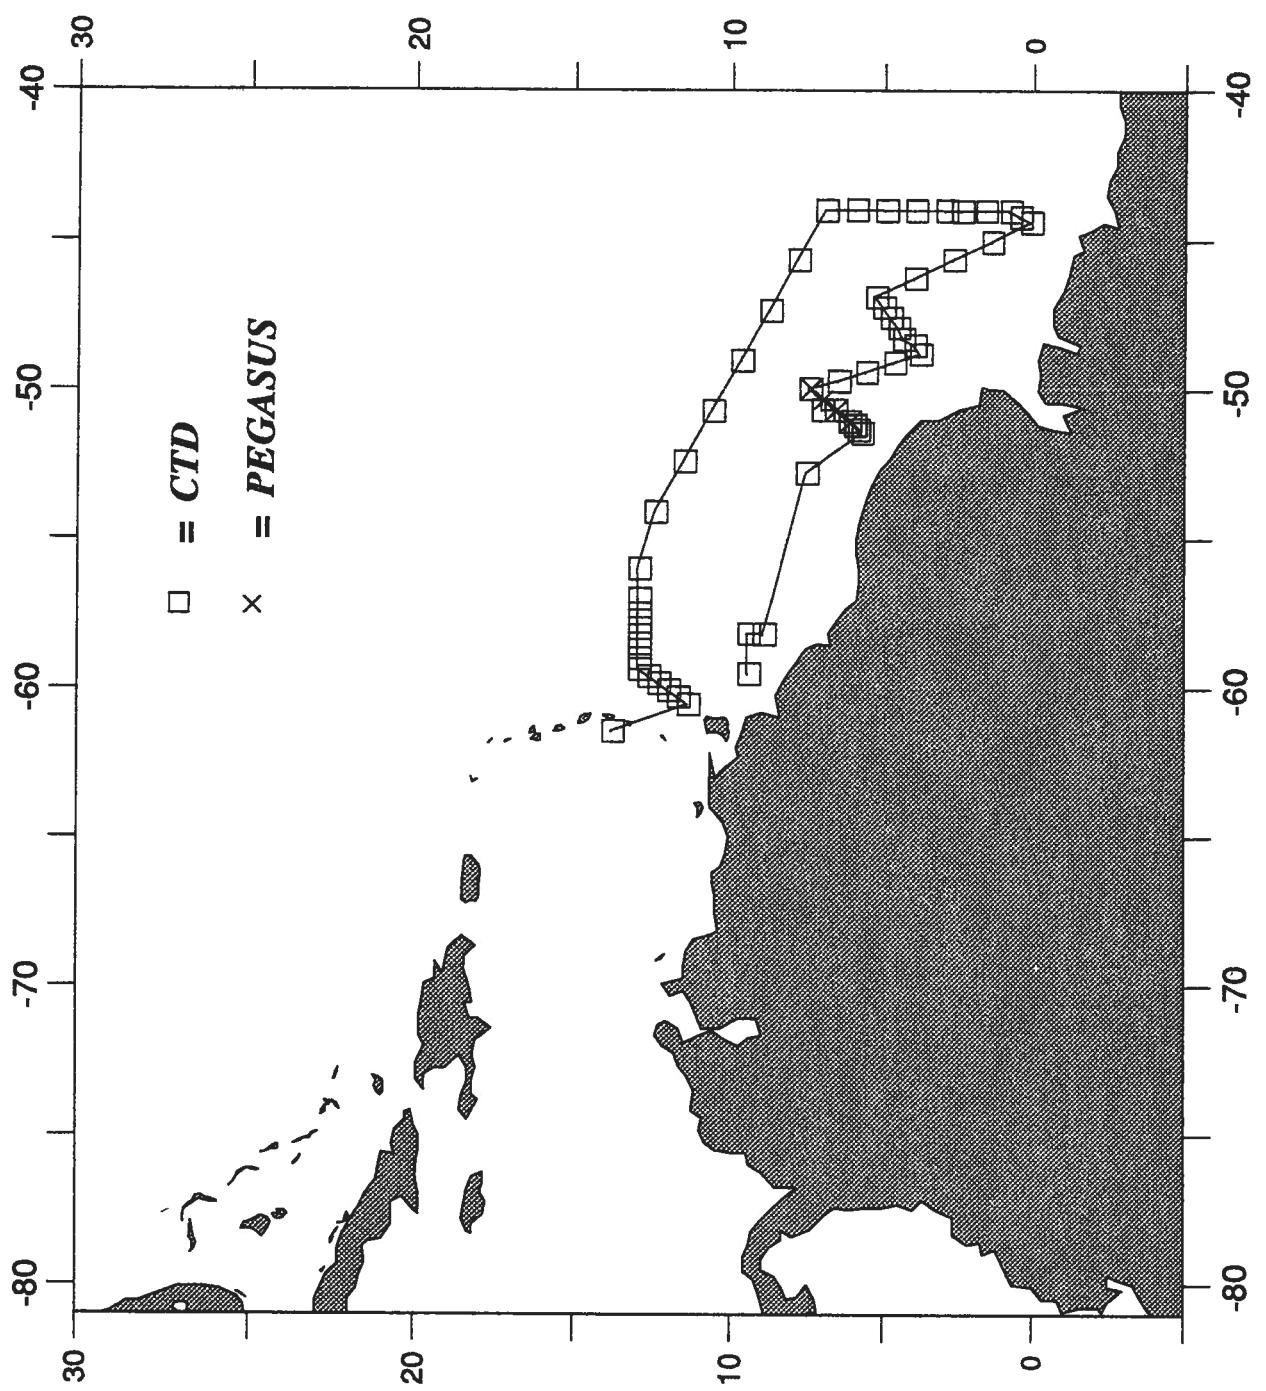

Figure 2. STACS cruise track for August 1989 showing CTD and Pegasus sampling stations.

Table 1. Types of Data Collected by Cruise.

Cruise	Vessel	Dates	Pegasus	CTD	XBT
February 1989 (AL-89-03-STACS)	ALBATROSS IV	1/24-3/16/89	5	80	64
August 1989 (MB-89-04-STACS)	MALCOLM BALDRIGE	8/22-9/22/89	4	54	110

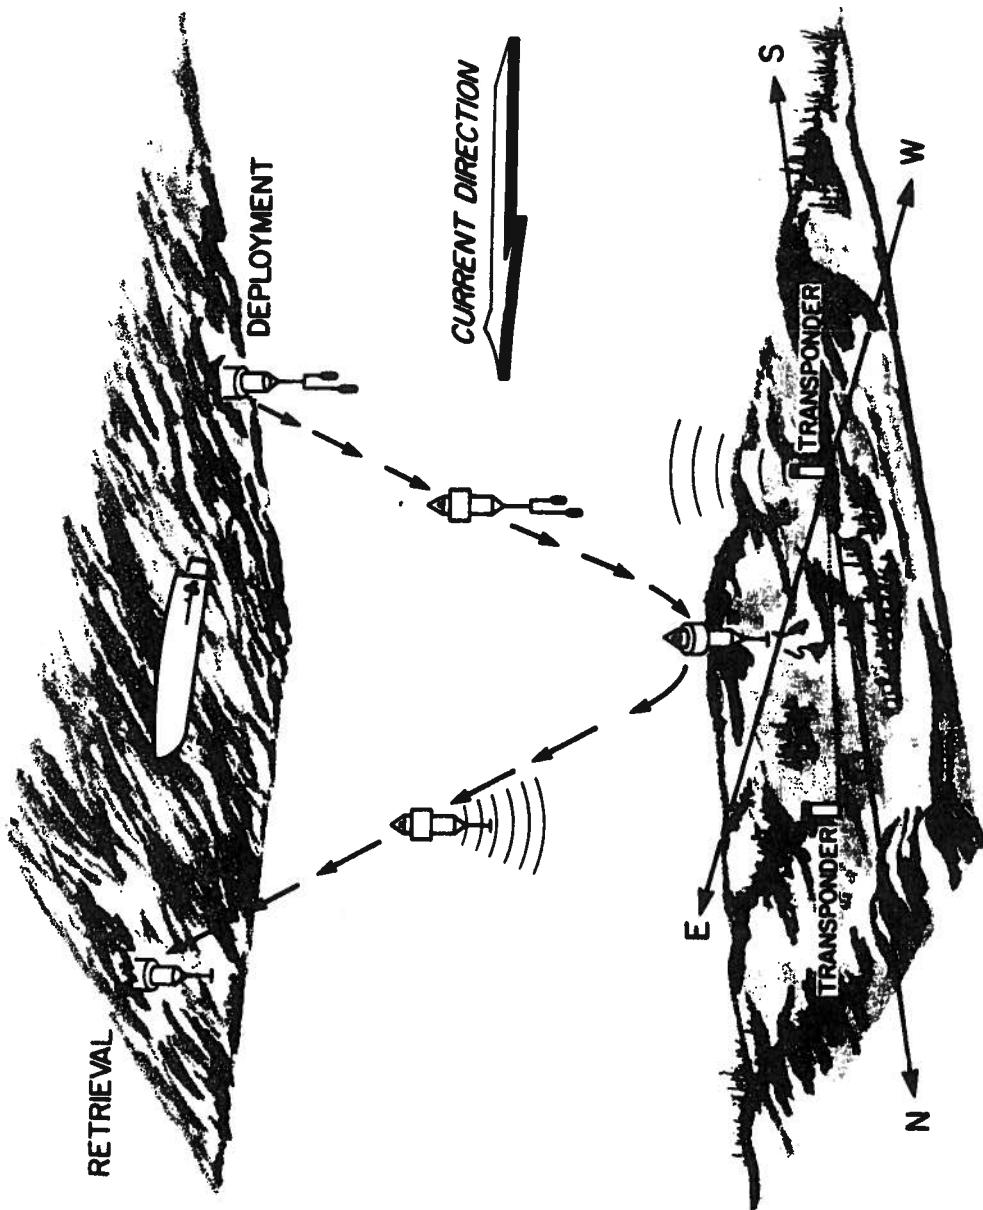

Figure 3. Schematic of the Pegasus current profiler.

sealed within. A flotation collar attached to the exterior of the cylinder provides the instrument buoyancy. Pegasus houses a transducer/receiver, a thermistor and a pressure sensor. When the Pegasus is in the water, its transducer interrogates two fixed transponders on the ocean bottom at a frequency of 10 KHz at an interval of eight or sixteen seconds. Each transponder responds at a different frequency. The Pegasus internally records the acoustic travel times from the transponders, along with temperature and pressure. Transponder frequency pairs are alternated between stations in order to avoid interference from adjacent stations.

The instrument is weighted at the beginning of the drop and falls at a rate between 20-50 cm/sec. This rate may be adjusted by adding or removing weights. External weights are released by a bottom trip mechanism when the weights touch the ocean floor or by a pressure release when the Pegasus reaches a predetermined depth. The instrument ascends at approximately the same rate as it descends.

Each Pegasus station is defined by a unique geometry (see Table 2). A mean sound velocity profile for each station is used to convert the acoustic travel times from the transponders to the instrument into ranges in meters. The baseline becomes the base of a triangle which is projected onto the bottom. The X and Y coordinates of the instrument at each pressure can then be determined.

Following a Pegasus cast the contents of the instrument's solid state memory are transferred to a Hewlett Packard 85 computer for conversion to decimal values and storage on flexible diskettes. The conversion of raw data to a velocity profile is done on an HP-86 in three steps: editing, calibration and velocity computations. Following is a brief description of each step.

1. Editing

Two files are created for each Pegasus cast: an ASCII character header file on magnetic tape containing cast information and a multi-record data file on magnetic disk. Each record contains decimal values of the original Pegasus memory address, corresponding pressure and temperature sensor output counts and two travel times significant to 10^{-4} second. HP-86 BASIC programs allow graphic display and printed listings of the data for preliminary evaluation of data quality.

Errors can be introduced into the raw data due to instrument hardware errors and into the travel times by acoustic propagation irregularities such as the detection of reflected instead of direct path signals. Erroneous points are hand edited from the record and replaced by points estimated by a low order polynomial fit.

2. Calibration

Prior to each research cruise the Pegasus pressure sensor is calibrated to produce second order polynomial fits of pressure counts versus pressure in decibars (db). Standard deviations from the fits over the working range of the sensors are generally on the order of 1 db. After the raw data has been edited the pressure counts are converted to decibars. Pressure is further smoothed with a five point running mean. Cast limits (surface/bottom/surface)

Table 2. Summary of Pegasus Station Geometry off Abaco Island.

Station	Transponder Parameters				Baseline Length (m)
	Latitude (N)	Longitude (W)	Frequency (KHz)	Depth (m)	
15	26°30.83'	76°19.01'	12.0	4810	4296
	26°31.74'	76°21.55'	13.0		
16	26°32.28'	76°30.10'	11.5	4855	4892
	26°32.20'	76°33.15'	13.0		
17	26°35.48'	76°39.30'	12.5	4050	3937
	26°33.72'	76°39.31	12.0		
18	26°32.67'	76°45.23'	13.0	3600	3755
	26°30.53'	76°44.88'	12.5		
19	26°33.11'	76°50.85'	12.0	800	1465
	26°32.22'	76°50.92'	11.5		
34	26°29.90'	76°07.22'	12.5	4810	4197
	26°29.71'	76°09.61'	12.0		
35	26°29.31'	75°32.34'	12.0	4610	4038
	26°29.44'	75°29.94'	12.5		
36	26°30.20'	74°32.97'	12.0	4460	1665
	26°30.12'	74°30.31'	12.5		

are recorded in the header file and the data are split into downcast and upcast files containing two travel times and pressure (db).

3. Velocity Calculation

Given the transponder depths, baseline length, pressure and the travel times, the Pegasus position can be determined. Each station has an associated sound velocity profile used to calculate harmonic mean velocity and thus convert acoustic travel times to distance for input into the position equations. The resulting profiles of X and Y position (in unrotated baseline coordinates) versus depth are smoothed with a seven point convolution. The resulting U and V velocity components are then rotated into a true geographic coordinate system. Each cast produces two profiles: one represents the downcast portion and the other the upcast. Only one profile from each cast is chosen based on a subjective comparison of the up and down profiles and these data for each cruise are presented by increasing cast numbers in Appendix A. The positions represent deployment locations rather than the transponder positions listed in Table 1.

B. CTD Data

1. System Description

The Neil Brown Instrument Mark III CTD system used in STACS includes pressure, temperature, conductivity and oxygen sensors.

The instrument scans at a rate of 30 scans per second. The descent rate is approximately 30 meters per minute to a depth of 200 meters then increases to 60 meters per minute for the remainder of the cast. CTD values are averaged in one decibar increments. Appendix B contains graphic representations of CTD profiles arranged by cruise and cast number. CTD values are listed at selected depths.

2. Calibration

Laboratory calibrations are used for the CTD pressure and temperature sensors. CTD pressures are assumed to be accurate to within \pm 6.5 db and CTD temperatures to within \pm .005°C. Bottle salinities are collected using a rosette sampler lowered with the CTD, with the final values determined using a Guildline Autosal unit. The bottle salinities are used for calibration of the raw CTD data using the methodology described below.

- a. The bottle salinities are edited for obvious bad values by examination of the residual differences between bottle and CTD salinities over the entire water column and by means of graphical comparisons with previous regional STACS and TTO (Williams, 1986a,b) temperature/salinity relationships in the deep water.
- b. The uncalibrated CTD salinity vs. pressure profiles are examined for conductivity sensor changes by examination of the time history of the residual differences between the edited bottle values and the CTD salinities, and divided into calibration subgroups if necessary. An iterative least squares regression is run on the residual (bottle minus

CTD) salinity vs. pressure data sets for each subgroup, and linear or polynomial fits are obtained over appropriate portions of the water column.

- c. The uncalibrated CTD salinity profiles are corrected using the results of the regressions, and the TS correlation is again compared with the bottle salinity values and the historical data set as a final quality check. The calibrated CTD salinity and temperature data are despiked, and a final data set subsampled to 2 db spacing is produced.

Discussions of the bottle salinity quality and CTD performance for the individual cruises, and tabulations of the respective calibration corrections, follow.

February-March 1989:

During the February-March 1989 cruise the bottle salinity data quality was high, and little editing was necessary. However, the CTD performance was atypical in terms of the size of the correction needed. The first CTD, used for casts 1-24, required a correction of .071 ppt. This is an order of magnitude larger than previous STACS CTD salinity calibrations, even though the CTD sensors had been recently calibrated. However, the standard deviation around the .071 ppt was only \pm .002 using 95% of the bottle values, indicating high precision.

Between casts 24 and 25 the CTD was changed, and the second CTD also showed a larger than normal offset in the other direction, $-.011 \pm .002$ ppt. During cast 40 rough weather caused the instrument to hit the side of the ship, which caused a small depth dependence in the required correction to develop. The Autosal malfunctioned during the running of the bottle salinity samples for the last 12 casts. These casts were taken off Abaco, the Bahamas, where the TS correlation is highly predictable, confirming that the CTD sensor calibration had remained steady to at least .003 ppt.

A plot of the time history of the CTD correction is given in Figure 4, and the statistics of the regression analysis for the three calibration subgroups are tabulated below. Plots of the delta (bottle-CTD) vs. pressure values are shown in Figure 5.

Casts Calibration Correction

1-24 $ds = .071 \pm .002$ ppt using 95% of the bottles

25-40 $ds = -.011 \pm .002$ ppt using 90% of the bottles

41-80 $ds = -.010 - 1.62e^{-6} * \text{pressure} \pm .002$ ppt using 95% of the bottles

August-September 1989

During the August-September 1989 cruise the bottle salinity data were also of high quality. However, the CTD which was used for casts 3-18 showed a pronounced drift within the range of .040 to .020 ppt, and needed to be calibrated on a cast-by-cast basis. Casts 19-54 were done using another CTD unit, and showed agreement with the bottles of $.000 \pm .002$ ppt, in other words requiring no post-cruise calibration correction. Casts 1 and 2 did not have

FEB89

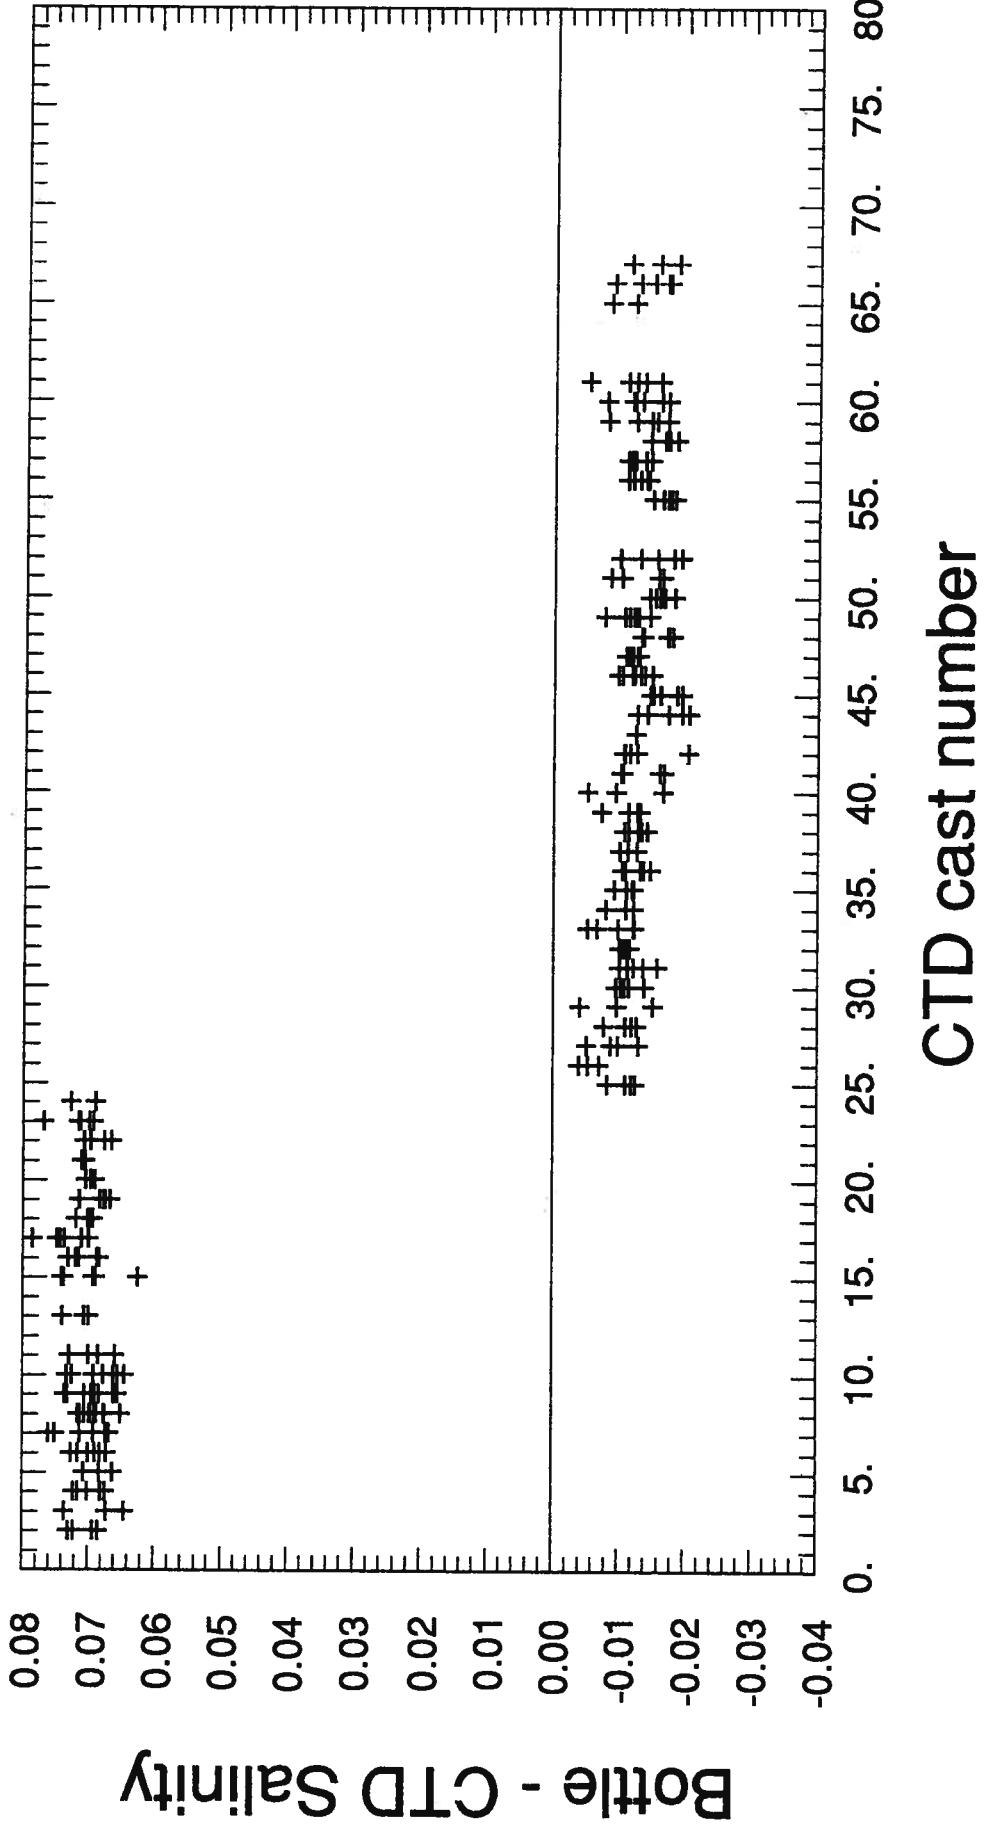

Figure 4. Time history plot of bottle minus CTD salinity vs. cast number for the February 1989 cruise.

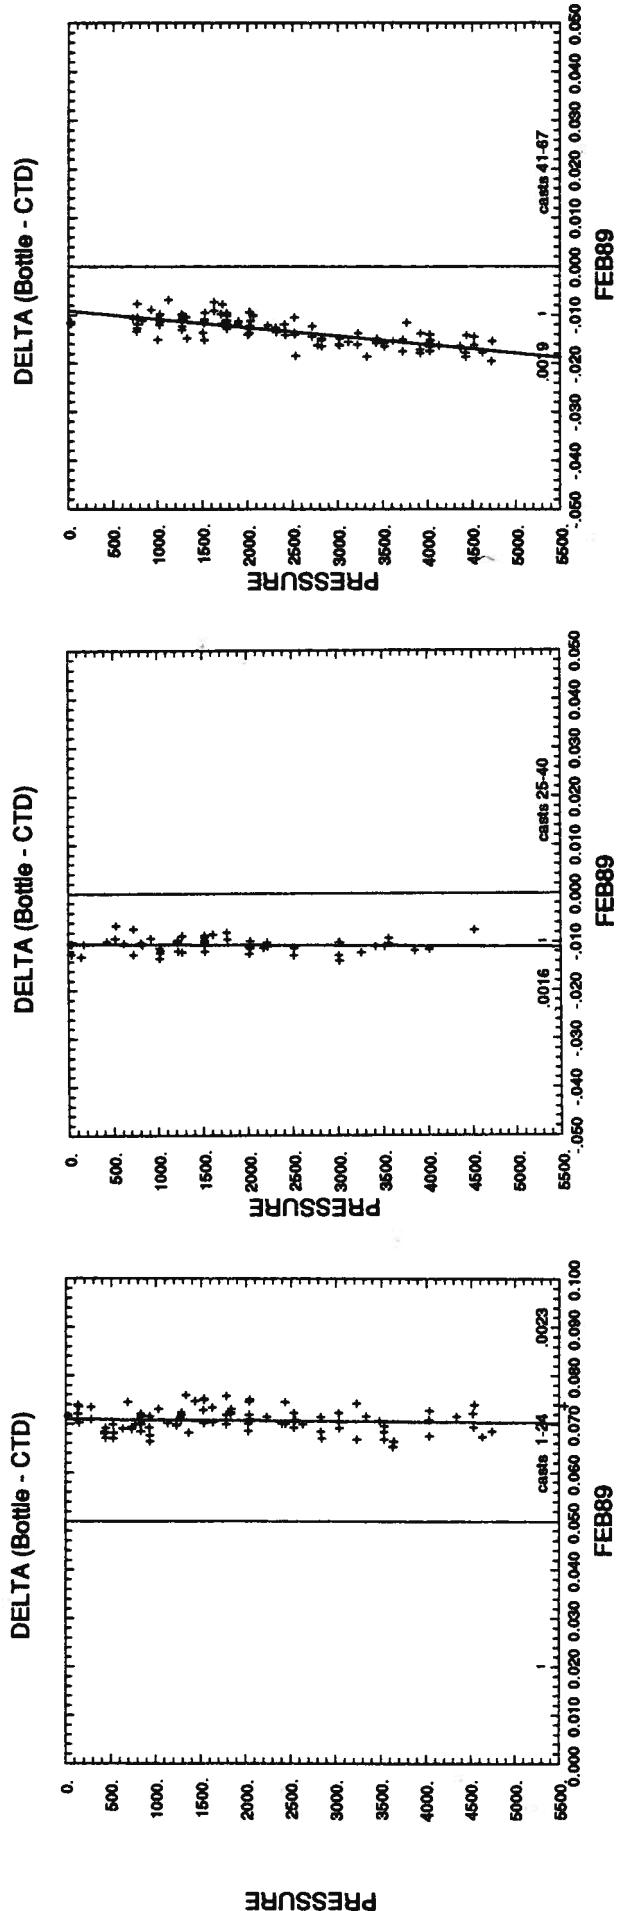

Figure 5. Calibration regression analyses for the February 1989 cruise. IV. ACKNOWLEDGMENTS

The extensive efforts of the officers and crew of the NOAA Ships ALBATROSS IV and MALCOLM BALDRIGE are gratefully acknowledged. Contributions by scientific and technical personnel Bob Molinari, Doug Anderson, Bob Roddy, Warren Krug, Mike Minton and Dave Bitterman of NOAA/AOML are greatly appreciated.

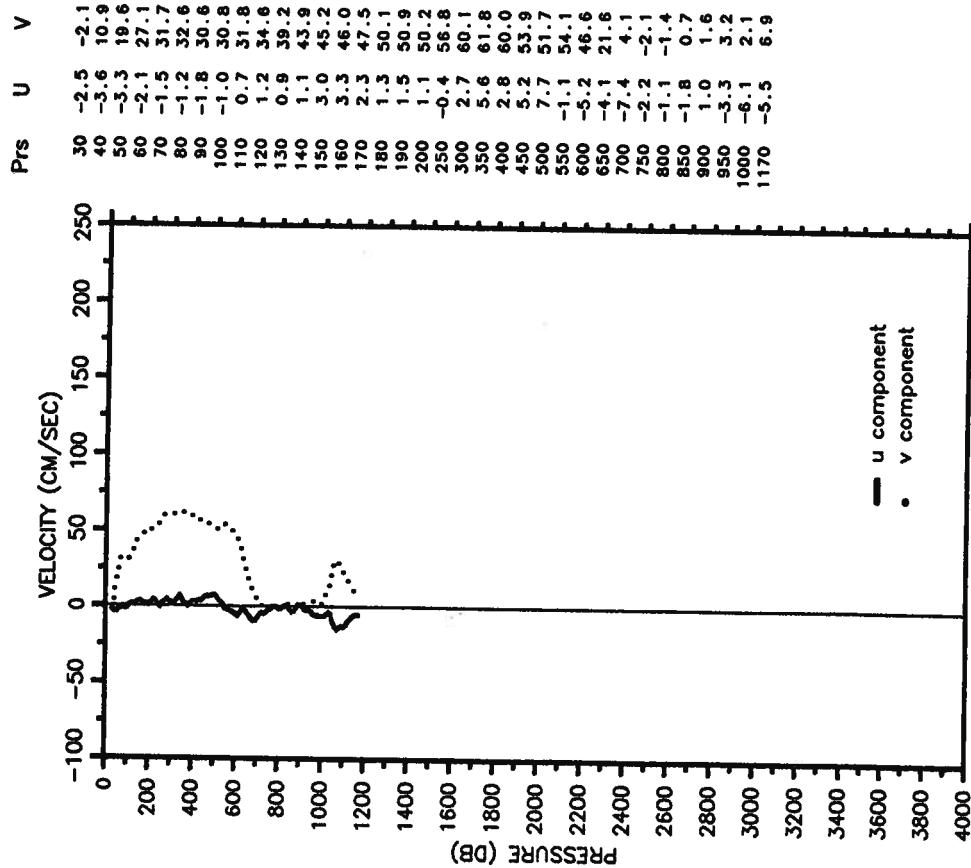

APPENDIX A: PEGASUS DATA

Casts are presented by cruise and increasing cast number. The cruise number and vessel, Pegasus cast and station number, Julian day and time, and position are shown at the top of each plot. "U" represents the east component of velocity. "v" represents the north component. Casts where there are no data values given for the U and V components indicate that the transponders signals were not being received by the Pegasus instrument at the given depth.
